An Address
ON
MALIGNANT DISEASE OF THE NASAL PASSAGES: ITS DIAGNOSIS, PATHOLOGY, AND TREATMENT.

Delivered at the Medical Graduates' College and Polyclinic

BY W. STUART-LOW, F.R.C.S. ENG.,
SURGEON, CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL; AND LECTURER ON RHINOLOGY AND OTOLOGY, MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, CHENIES STREET, W.C.

LADIES AND GENTLEMEN,—My reasons for selecting this subject of malignant disease of the nasal passages, its diagnosis, pathology, and treatment, on which to address you this evening are: first, that you will find that in nearly all the writings of the authorities it is very unsatisfactorily and scantily dealt with, and many statements made with reference to it are very contradictory and unreliable; secondly, that I have recently met with cases which illustrate and emphasise the importance of clearly comprehending the urgent necessity for early diagnosis if the patient's life is to be saved, and again, founding my conclusions on cases I have actually come in touch with, I very much doubt if the urgent necessity for clearer views about malignant disease of the nose and the fatal results likely to happen if it is not diagnosed early are sufficiently grasped by those first seeing these cases—viz., the general practitioners.

MALIGNANT DISEASE OF THE NASAL PASSAGES AND ANTRUM: OPERATION BY THE CANINE FOSSA ROUTE.

CASE 1.—One of these cases which I have referred to was that of a young woman, 22 years of age, sent to my clinic from the Royal London Ophthalmic Hospital (Moorfields), and it serves to illustrate three points in the history of malignant disease of the nasal passages—that it may begin outside the nose—be of extrinsic origin; that the disease, while ultimately presenting quite characteristic symptoms, may in its early stages appear in unusual and obscure forms; and that, if operated upon in time, malignant disease of the nose is often readily amenable to surgical treatment. This young woman had been a patient at Moorfields, whither she had gone complaining of pain in the left eye, but not of a constant or severe character. The sight was not affected, but there was some watering of the eye, and the vessels looked congested. About three weeks before being sent to my clinic some swelling had supervened under the left eye, extending on the cheek. As nothing definitely wrong with the eye could be discovered, she was sent to me on the supposition that there might be something in the nose or its accessory sinuses to account for the symptoms. The only thing noticed on carefully examining the interior of the nose was enlargement and œdema of the middle turbinal on the left side, and some narrowing of the nasal passage on this side from bulging inwards of the outer wall; but on transillumination no infra-orbital crescent was discovered on this side, the whole cheek being uniformly dark. The pupil did not illuminate, and she said that she did not perceive the light shining into this eye as on the right side. It was clear, then, that the light was not being transmitted through the antral cavity, which was almost certainly occupied by thick fluid or some solid substance. The next step in the diagnosis consisted in exploring the antrum from the nose by means of Lichtwitz's puncturing trocar and cannula. On this being done a few drops of blood exuded from the cannula, but no pus; this pointed to something of the nature of a growth, which was made more likely still when on blowing air through the cannula only blood was forced out.

The bloody discharge was preserved and handed to the pathologist, who reported that it contained cells indicating the presence of a growth in the antrum—the most reasonable solution of the case. Iodide of potassium and liquor arsenicalis were prescribed, and being so young the patient was kept on these preparations for a fortnight in the hope that resolution of the growth might take place. No improvement resulted; indeed, the facial swelling steadily increased, almost closing the eye, and the nasal passage on the left side became narrowed and more blocked to respiration. She was therefore entered as an in-patient. I may mention with reference to this case that at the operation—to be detailed later—through the canine fossa the antrum was found to be almost completely occupied by a vascular and firm tumour; it was most firmly attached to the posterior wall from which it had originally sprung, and was pressing through the thin inner wall into the nose, this fact explaining the narrowing of the passage. Dr. Wyatt Wingrave, the pathologist, pronounced it to be a "spindle-shaped fibroid sarcoma."

This case serves to illustrate the fact that malignant disease may invade the nasal passage proper from without, from the cavity of the upper jaw—be, in fact, extrinsic in its origin as regards the nose. With reference to the diagnosis, the most likely conditions that you are apt to confound such a case with are cysts of the antrum (mucocele) and dental cysts. A very large dental cyst invading and expanding the antrum wall may very easily be confused with malignant disease of the upper jaw, and so might the superficial and facial swelling and expansion of the bone brought about by a mucocele of the antrum; but in both of these the pain would be slight, whereas in malignant disease it is commonly severe, of a sharp, shooting, radiating, neuralgic type. On transillumination, again, the cysts are clear and the malignant growth opaque or dark; and on puncturing the cysts clear fluid is found, while in tumours either no fluid is obtained or only a few drops of blood. It was decided to operate by the same method as was adopted in the following case, which I will first give an account of as it illustrates certain features of malignant disease of the nose that I am anxious to emphasise.

CASE 2.—The second case illustrates the fact that malignant disease may begin on the outer wall of the nose and invade the antrum secondarily.

A woman, 35 years of age, had suffered for two years from unilateral nasal bleeding, and the nasal passage had been gradually getting more and more blocked. The hæmorrhage had been more and more frequent during the last six months, and sometimes severe. She had suffered little or no pain in the nose or face and complained chiefly of a more or less constant sanious and serous discharge from the left side of the nose, and of stuffiness on this side. There was no swelling or visible symptom to be detected on the outside; but on inspecting the interior the left nasal cavity was found to be full of what proved on palpation to be a soft, vascular, pale, red mass of growth; it was filling up the cavity and obscuring the turbinals. On transillumination this side of the nose was quite dark, and the antrum on the same side was partially obscured also. Cocaine solution having been applied, a piece of the growth was snared away, when the hæmorrhage was very severe; indeed, necessitating repeated packing with adrenalin solution, and that the patient should rest in the horizontal position for over an hour before being able to return home.

The pathologist pronounced the tumour to be one of columnar-celled epithelioma. Operation was decided upon, and in view of the fact of the vascularity of the tumour large doses of calcium lactate were administered during the two following days, and a dose of one drachm was given the evening before the operation, which was performed very early in the morning. I am certain that patients withstand the shock of an operation much better if it is performed in the early morning, and if that time be chosen much may be placed to the credit side of the patient as regards rapid and sound recovery.

I would like to be emphatic about two points with reference to this case: one is the diagnosis, and the other the method of operation. This patient had suffered from unilateral bleeding from the nose for two years, and the passage had been gradually becoming more and more blocked. Hæmorrhage from the nose may go on for years, and yet the cause be quite an innocent and simple one, such as septic ulceration or encrustation; but, if progressive obstruction is a concomitant symptom, strict attention should be given to the diagnosis and causation, as it is much more likely to be of a serious nature. Pain is not to be relied on as a danger-signal. This patient had experienced little or no pain, and it may only be when damming up of secretions, tension and pressure upon and implication of nerves occur that pain is prominently manifest.

217156

At the operation, in anticipation of severe hæmorrhage, laryngotomy was first performed, and the pharynx and larynx packed with captive sponges, the head and shoulders being well raised so that a good view of the interior of the nose could be obtained. I decided not to incise the face and thus blemish the patient for life, but to try to remove the tumour by the canine fossa route. The gingivo-buccal fold was freely incised from beyond the middle line in front backwards to the canine ridge, and the soft structures raised upwards, including the periosteum and the lateral cartilages of the nose. In this way, and by forcible retraction, nearly the whole of the anterior and lateral surface of the superior maxillary bone can be well exposed. The anterior wall of the antrum was then almost entirely removed and the contents of the antrum evacuated. The outer wall of the nose was then freely taken away, the ascending process of the superior maxilla not being touched; this is not at all necessary, as perfectly satisfactory access can be obtained to the interior of the nose without one's doing so.

In this particular case I readily removed a large mass of growth which had extended up into the middle turbinal region. The canine fossa route into the interior of the nose is an excellent method of operation in extensive or malignant disease of the nose, and has the great recommendation that no mark is made or left on the face.

The operation I prefer and have described as employed successfully in both of these cases is a modification of Rouge's method, and is preferable to such external operations as Langenbeck's, where a flap is turned down from the outside of the nose.

SARCOMA OF THE NOSE, ETC.

The following case illustrates the occurrence of sarcoma in the nose, which most frequently arises in elderly people, but may occur at any age as a primary tumour. It is sometimes seen well forward on the septum as a single, soft, sessile, very vascular, and uniform swelling; it may be smooth or rough, and readily bleeds if touched. Frequent and severe epistaxis in a patient with a sessile polypus-looking growth on the nasal septum would suggest to the mind at once a sarcoma, and if such a tumour be removed early the prognosis is good.

CASE 3.—A young woman, aged 27 years, a domestic cook, came to the hospital complaining of severe unilateral nasal bleeding which had been going on at intervals of a few days for over a year. She had had occasional shooting pains up the side of the nose and the passage had been becoming more and more blocked. On examination a very vascular swelling of the size of a sixpenny-piece was seen on the nasal septum at about its middle. This was soft and very florid-looking and bled very much on being lightly touched. A piece was snared off, and the pathologist pronounced it to be small round-celled sarcoma.

The patient was admitted to the hospital, and a general anæsthetic having been administered and the posterior nares firmly plugged, the growth was curetted away. It was found to have eroded the bone; the cartilaginous septum was perforated, the tumour having invaded the soft tissue on the opposite side. The base of the cavity left after excavating the sarcoma was then touched with liquid acid nitrate of mercury and the nostrils packed with gauze. Two years have now elapsed, but no recurrence has taken place.

Sarcoma is the form of growth most frequently met with in the interior of the nose. It very rarely originates directly from the mucous membrane, but in the great majority of cases is apparently derived from the periosteum or perichondrium of the bony or cartilaginous framework of the nose.

Sarcoma may originate in any part of the nasal fossæ, especially in older patients. It may start at the base of the skull, from either the sphenoid or the cribriform plate of the ethmoid. From these positions the growth may extend to the fossæ, the accessory sinuses, and the naso-pharynx, and by pressure bring about that separation of the eyes and flattening of the nose likened to a frog's face, with hideous deformity.

The two varieties of sarcoma that preponderate over all others are the round-celled and spindle-celled. The round-celled are found most frequently springing from the boundaries of the maxillary antrum. They are also met with in the ethmoid region, originating in the bony cells of which this part of the nasal interior is largely composed. Sometimes round-celled sarcoma is encountered in the frontal sinus. The spindle-celled sarcomata are most often seen originating from the nasal septum.

Giant-celled sarcoma is very rare and has been observed in different parts of the nasal cavity.

LYMPHO-SARCOMA.

A form of sarcoma that is very rare is the lymphosarcoma, and this is met with almost exclusively in the naso-pharynx; it commences in the lymphoid structures found in the roof and sides of this cavity, and from these positions may invade the nose from behind. When present, this growth is mostly found associated with similar tumours in the faucial tonsils and accompanied by great enlargement of the cervical lymphatics. The following was a case of this kind sent up from the country to my clinic about two years ago.

CASE 4.—The patient was a man, 38 years of age, who complained of gradually increasing stuffiness of the nose, difficulty of swallowing, and deafness. He was found to have a forward bulging of the soft palate through which on palpation a firm elastic swelling was to be made out, and the growth was discovered to extend throughout the cavity of the naso-pharynx, quite filling it and protruding into the nose from behind. There was also direct extension laterally into the superior deep cervical glands, and posteriorly into the posterior triangle of the neck. The glands were first removed under local anæsthesia, as the breathing was too disturbed to warrant an anæsthetic. A few weeks later the tumour in the naso-pharynx was dealt with by first performing laryngotomy and plugging the larynx. The palate was then split and all the growth rapidly removed. The patient recovered satisfactorily, but in six months had a secondary growth in the liver which extended to the skin. There was no recurrence locally at the sites originally operated upon. There is no doubt that these cases ought always to be early and radically treated at the first seat of the trouble, and if this is done properly no recurrence will occur.

NASAL POLYPI BECOMING SARCOMATOUS.

The question as to whether nasal polypi, mucous and fibrous, are capable of, and given to, taking on a sarcomatous change is a much discussed and vexed one. There is no doubt, as I have often observed, that after mucous polypi have existed for many years (some patients suffer from these growths for a life-time) and have been frequently removed the polypi tend to become more and more vascular and fibrous. This suspicious change, sometimes symptomatic of impending sarcomatous development, commences at the deep parts of the growth, and when detected should ever suggest to the mind of the surgeon that malignant disease may be coming, and that one should make a certainty of this by removing a piece and having a pathological opinion upon its nature. There is little doubt, either, but that innocent and malignant polypi may co-exist, growing side by side, and if sufficient of the tumour is not taken for pathological examination a wrong conclusion may be arrived at by removing only the more manifest and abundant innocent growths. The following two cases lend support to the view that innocent mucous polypi may take on malignant change.

CASE 5.—A man, 70 years of age, came to the clinic of one of my colleagues some years ago complaining of nasal stuffiness and occasional nose-bleeding. The nostril on the left side was found to be packed with a fibrous, fleshy, hæmorrhagic-looking mass which bled freely on being probed. He gave a history, which was verified, of having attended for 25 years as a private patient at a well-known specialist's, and afterwards at his hospital, and of having had polypi snared away at intervals during this prolonged period. The tumour was now found to be sarcomatous, and as the maxillary antrum was quite dark on the same side on transillumination surgical treatment was decided upon. An extensive operation, in which the upper jaw was removed and the base of the brain exposed, was carried out, but the patient died the same evening. At the post-mortem examination the disease was found to have invaded the orbit, the antrum, and the cranium, and was proved to have become sarcomatous in its deeper parts.

CASE 6.—This case was one of my own, that of a man, 45 years of age, who had suffered from mucous polypi in the

nose all his adult life. These had been repeatedly snared away at varying intervals, but during the last year hæmorrhage had become a prominent feature of his case. The antrum on the left side being perfectly dark on transillumination, it was decided to enter the nose by the canine-fossa route and try to remove all the growth, which turned out to be a sarcoma, by this method. Excellent access was in this way obtained, but the disease was found to have extended well up into the ethmoid region, even involving the middle and posterior ethmoid cells. Unfortunately, meningitis commenced on the third day after operation and proved fatal in two days. This case, like the former one, emphasises the danger in attempting to carry out a complete operation when malignant growth supervenes upon or co-exists with nasal polypi.

CARCINOMA.

Carcinoma of the interior of the nose is most usually seen in the form of typical squamous cells, although originating in a mucous membrane covered with a ciliated epithelium. Such is perhaps to be explained by the fact that the appearance of a carcinoma is, in the majority of cases, preceded by an ozæna or an accessory sinus suppuration in which the ciliated epithelium undergoes a conversion into squamous, and so the way for the cancerous change is prepared. Most usually these carcinomata originate in the ethmoid region, practically from the roof of the nose.

In my opinion malignant disease of the nose is most liable to arise when the mucous membrane is thin and is a muco-periosteum, as in the sinuses and in the cells of the ethmoid region. If there is a state of desiccation and shrivelling of the protective mucous lining on the lower part of the nasal passages, and over the inferior turbinals, irritating, dry, and dusty air will be allowed to pass up into the higher regions, and so a chronic irritation will be maintained which becomes a primary factor in the causation of this diseased condition.

Those inheriting thin mucous membranes—for just as thick and thin cutaneous coverings are a matter of inheritance, so are thick and thin mucous membranes or inner skins—are most liable to cancer. Again, unfavourable surroundings and occupations such as necessitate the inhalation of dry, warm, and dust-laden air favour the development of cancer in the nose.

As distinguished from the nasal passages proper, in the accessory sinuses cylindrical-celled carcinomata are apparently more frequent than the squamous-celled variety. Carcinoma is more common in the antrum than in the frontal sinus. The following case will illustrate such a tumour.

CASE 7.—A woman, 45 years of age, came to my clinic complaining of severe pain of a month's standing, and of a swelling which was gradually increasing, situated on the left cheek. The swollen part was limited to a space of about the area of a half-crown, and was firm but elastic, and painful on deep pressure. This side was dark on transillumination, and on puncturing the antrum through the nose with Lichtwitz's trocar and cannula only blood exuded. On operating through the canine fossa the floor of the fossa was found to be eroded, and a mass of growth was seen protruding through the opening, spreading mushroom-like over the cheek under the cutaneous structures. The cavity of the antrum was found full of the tumour, which proved to be a columnar-celled epithelioma. It was freely removed, and the surrounding bony walls thoroughly scraped and rubbed with a strong solution of chloride of zinc. The patient did well, and no recurrence has taken place during the past two years.

SUMMARY.

In conclusion, there are some practical lessons to be learned from a study of this subject: 1. Pain is not to be relied upon as an indication of malignant disease in the nose. 2. Increasing and persistent stuffiness, especially if unilateral, is an important point as regards diagnosis. 3. Recurring and increasingly severe hæmorrhage, especially if unilateral, is always a suspicious symptom. 4. A combination of hæmorrhage and increasing stuffiness is often a serious indication of new growth existing. 5. The making of an early diagnosis is of great importance. 6. It is imperative to make a thorough and systematic examination in all obscure cases of nasal disease, and to remove early a piece of any obstruction in the nasal passages for a pathological report. 7. It is of great importance when there is malignant disease to operate as soon as possible after a diagnosis has been made to secure a successful removal. 8. It is advisable to adopt the canine-fossa route in operating for the extirpation of intra-nasal tumours. 9. Innocent and malignant polypi are likely to coexist.

THE ESSENTIAL CAUSE OF GASTRIC AND DUODENAL ULCER.

BY C. MANSELL MOULLIN, M.A., M.D. OXON., F.R.C.S. ENG.,

CONSULTING SURGEON TO THE LONDON HOSPITAL; VICE-PRESIDENT, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

LEAVING upon one side cases that are due to tubercle or to other specific agents, the starting-point of what is commonly known as a gastric or duodenal ulcer is the destruction by a process of digestion of more or less of the thickness of the wall in one particular spot. This is the work of the gastric juice, aided by inflammation, unless, as sometimes happens, the destructive process is so sudden and so acute that there is no time for this to come into play. Everything that injures the tissues, or lowers their vitality, or interferes with their nutrition sufficiently renders them liable to this. It is evident, therefore, that there must be many different causes, and that in many instances, if not in all, more than one are at work at the same time.

Immunity.

Tissues that produce gastric juice or are normally bathed in it are not affected by it, so long as they are healthy and uninjured. They have acquired immunity in the course of development. Others are killed by it, but they are not. So long as the mucous membrane lining the stomach and the first part of the duodenum is living and healthy the gastric juice is not able to harm it. Lower down in the bowel the degree of immunity grows less and ultimately disappears. To what this immunity is due is not known. There is some reason to think that living tissues in general possess the power of resistance in a higher degree than dead ones, but other living tissues, with the exception of a few organisms, such as some parasitic entozoa, are soon killed and then at once digested. It may be that the power of resistance is dependent not so much upon the life of the cells as upon some property or substance that is contained in them, something, perhaps, of the nature of an antiferment. The blood undoubtedly does possess an antitryptic power that varies in strength under different conditions; and there may be some substance of a similar character in the cells of the gastric mucous membrane. But it must be understood that no such thing as an antiferment has been isolated, and that the name is little more than an expression to describe certain phenomena, the nature of which is not known. All that can be said is that if the power of resistance is not dependent upon the life of the tissues in question, at least it disappears with it; and that when killed or badly injured in any way, the mucous membrane of the stomach and first part of the duodenum does not appear to offer an appreciably higher degree of resistance to the gastric juice than any other similar tissue.

This immunity is not shared by the submucous and muscular coats. The deeper layers of the mucous membrane possess it to some extent, and it is reasonable to associate this with the deep extension of the epithelial layer. But if the whole thickness of the mucous membrane is destroyed at any one spot, so as to leave the submucous or muscular coat exposed to the gastric juice, the corrosive process continues, and either the wall gives way, or if there is sufficient time for inflammation to set in, a protecting barrier is formed by the thickening of the serous coat, or by its fusion with the corresponding layer of some neighbouring organ. When this occurs, a balance of a more or less fluctuating character is struck between the corrosive action of the gastric juice on the one hand, and the resistance of the inflamed and irritated tissues upon the other. Sometimes the one gains the upper hand; sometimes the other. The ulcer at one time grows deeper or wider; at another it remains stationary or even contracts; but when it has once reached this stage it has become chronic, and is to be regarded no longer as simply one of the results of a general morbid process, but as a disease of itself, requiring special treatment.

The site of a gastric or duodenal ulcer is always determined

by some local cause. The commonest situation, for instance, is either where the mucous membrane is thickest and softest, and the lymphoid tissue most abundant, or at those points where pressure is greatest or the surface most exposed to injury. But in certain cases gastric ulcers are due entirely to local causes, and these, because they are simpler, I shall deal with first.

Direct Causes.

Gastric ulcer, when of purely local origin, is nearly always due either to injury or to some gross vascular lesion, suddenly cutting off the blood-supply. It may, for example, be caused by direct violence. In several instances I have known hæmatemesis follow a blow upon the epigastrium, or a sudden muscular strain, in men whose previous history gave no reason to suspect the presence of an ulcer; and in one of these the diagnosis was subsequently confirmed by operation. In all probability there had been considerable bruising of the mucous membrane, with hæmorrhage into its substance; or perhaps a rent. Owing to the conditions present at the time the lesion did not heal, but developed into an ulcer, which at the time of the operation presented all the ordinary features of a chronic ulcer. Several similar cases have been recorded.

The degree of violence necessary to produce this result in any individual case naturally differs very widely. One factor of great importance is the state of the gastric circulation. When the stomach is actively engaged in the process of digestion the force need not be very great. If the mucous membrane is in that state of intense congestion which sometimes results from pathological causes the slightest touch is sufficient. It has even been suggested that the wearing of ill-fitting stays by women of the domestic class, who have constantly to be stooping at their work, may be one of the reasons why gastric ulcer is of such frequent occurrence among them.

Swallowing corrosive poison is another occasional local cause. In several cases under my care in which an attempt had been made to commit suicide by swallowing strong hydrochloric acid, ulcers were caused in the œsophagus and at the pylorus. The intermediate portion of the stomach escaped. If the patient survives, these ulcers may heal like ordinary wounds or may persist and become chronic. In either case they often leave behind them a serious degree of cicatricial contraction, for which I have twice had to perform gastro-enterostomy. It is a fair deduction from this that in ordinary circumstances, when the contents of the stomach are only slightly more irritating than usual, the pyloric portion is more liable to be injured than the rest of the interior; and for this reason, among others, is especially likely to become the seat of ulceration.

Embolism, cutting off the blood-supply from one particular section, is one of the best known local causes. In patients who have died with endocarditis, every stage of ulceration and every grade in the development of ulcers from early infarction of the mucous membrane to complete destruction may be found on post-mortem examination, and the whole process can be traced from beginning to end. The same thing has been proved experimentally by many observers, and in operating upon cases of recent gastric ulcer, I have often seen unmistakable evidence of this—flame-shaped patches of hæmorrhagic exudation, due to embolism, in the immediate neighbourhood of recent erosions. It was impossible to avoid the impression that both had originated from the same cause. In the one the protection of the epithelial layer had been preserved, so that there was merely an infarction of the mucous and submucous layers. In the other this had been lost and digestion had taken place, leaving an erosion or an ulcer, according to the depth to which the destruction had extended.

In all probability embolism is the immediate cause of the gastric and duodenal ulcers that occasionally develop after injuries and operations, especially those involving bones. There is evidence to show that, apart from sepsis and septic infection, embolism is much more common in these circumstances than is usually believed. Attention is not attracted to it because, as a rule, the arteries that are blocked are small, and cutting off the blood-supply does not involve any striking consequence. It is, for example, a matter of very old observation that infarcts due to embolism of minute branches of the hepatic artery are of common occurrence in the liver after fatal accidents and injuries. Owing to their locality they are not noticed during life, but if the gastric branch were involved instead of the hepatic, and the other conditions were suitable, it can easily be understood that a gastric ulcer would follow. I have shown elsewhere that fatty embolism of the pulmonary capillaries occurs in every fracture, and that the particles of fat are carried through the vessels of the lungs into those of other organs. If this is so frequent in the case of fat, it is probably scarcely less common with particles of fibrin from the coagula in the minute vessels which are bruised or severed in every injury or operation.

Embolism also plays a part in the production of the gastric and duodenal ulcers that occur in the course of acute infectious disorders and in septic infection and intoxication, though it is seldom possible, owing to the action of the gastric juice upon the affected area, to demonstrate the presence of the obstruction. Analogous changes in neighbouring organs leave no room for doubt. But here there are other influences at work as well, and the ulcers are not due to local causes only. The presence of septic poisons circulating in the blood, possibly excreted in part by the gastric mucous membrane, cannot but have a strongly predisposing effect. They lower the vitality and the power of resistance of all the tissues, and by causing the intense congestion of the mucous membrane ending in hæmorrhage, so often present in these circumstances, they lead to such a condition of things that the least irritant, one which in health would leave no trace behind, is sufficient to cause an ulcer. The superficial erosions, as distinguished from genuine ulcers, so often found in these cases, are probably all caused in this way.

Embolism, therefore, must be regarded as an important and a proved cause for gastric ulcer, but though its capacity cannot be doubted, and though it furnishes some of the most striking and characteristic examples, it is by no means certain that apart from such affections as endocarditis and the others I have mentioned it is a frequent or even a common cause. In a large proportion of cases it is not possible to find any evidence of embolism, or to suggest a locality whence an embolus could have come.

Arterial degeneration is frequently present in the walls of the stomach in association with gastric ulcer. It has been described as occurring in recent acute cases. In chronic ones it is so common as to be the rule. In operating upon such cases I have been struck by the frequency with which it occurs in the mucous and submucous coats. The walls of the arteries are thickened, the muscular coat practically replaced by fibrous tissue, and the lumen seriously reduced in size. A similar change has been described by Miller in the walls of the gastric arteries in chronic dyspeptics, associated with degenerative or chronic inflammatory changes in the mucous and submucous layers. It is not probable that a change of this kind could ever be the immediate cause of ulceration unless it progressed so far as to lead to arterial occlusion, but it must have a predisposing influence, and there can be little doubt that it tends seriously to delay the healing of any ulcer when once it has been formed and helps to make it chronic.

The same that was said of embolism may be said of thrombosis. It certainly can act as a cause. Miller[1] has described a case in which numerous shallow ulcers, smaller in area than those generally found when the arterioles are blocked, were present on the gastric mucous membrane, caused by changes in the endothelial lining of the gastric veins with consecutive thrombosis. The intima was rough, the cells scarcely recognisable, and the lumen was narrowed and filled with shreds of adherent clot. A similar change in the intestinal veins had led to gangrene of the bowel. But though thrombosis may possibly play some part in the gastric ulcers that occur in chlorosis, and in the lesions that are met with in cases of septic intoxication and infection, it cannot be regarded as common.

The gastric and duodenal ulcers that are occasionally found after injuries to the brain and spinal cord, and those which are caused experimentally by subphrenic section of the vagi, and by injuries of the splanchnics and of the cœliac plexus, are also the result of local vascular lesions. Hæmorrhages, at any rate, are met with more frequently than ulcers, and the bases of ulcers, when they are of recent origin, are nearly always infiltrated with blood. The same thing is true of ulcers that occur in patients with heart

[1] Archives of the Pathological Institute of the London Hospital, vol. i.

disease other than endocarditis; but those which are occasionally found in Bright's disease, advanced jaundice, hepatic cirrhosis, and the like, are the product of the general morbid condition, the local cause, whatever it may be, doing little more than determine the exact situation.

Indirect Causes.

These varieties of gastric and duodenal ulcer are, however, all of them exceptional, due to exceptional causes, and chiefly of interest from the light they throw upon the method of development of the rest. In the vast majority of cases of what is usually meant when speaking of gastric or duodenal ulcer local agencies do little more than determine the actual site. The essential factor is the morbid condition of the mucous membrane, of which the ulcer is little more than a local accentuation. Acute ulcer of the stomach and duodenum is often regarded as if it were a disease of itself. It may be so when due to purely local causes, such as those I have already described; but in all ordinary cases the ulcer is little more than a secondary consequence. An ulcer may make all the symptoms worse and perpetuate them, but no matter how prominent it appears to be it is not the primary element. The essential factor is the morbid condition of the mucous membrane. It is only when an ulcer refuses to heal and has become chronic that it can be regarded as a disease of itself.

Up to the present time the existence of this morbid condition of the mucous membrane has attracted but little notice. During life there is seldom anything to call attention to it but an alteration in the secretory activity of the gastric mucous membrane and an occasional outbreak of hæmatemesis. In some instances the amount of hydrochloric acid in the gastric juice is said to be increased. In others the gastric secretion is excessive and apparently continuous, independent of the stimulus of food, for if the patient's stomach is washed out in the morning after many hours of fasting, it still contains 50 or 100 cubic centimetres of thin bile-stained gastric juice. Post mortem the only sign that points to it is the presence of a few erosions with some blood-stained spots and interstitial hæmorrhages. These are very significant when they are properly interpreted and understood, but they do little more than suggest what has been happening. It is only since the recent improvement in the gastroscope, rendering direct inspection of the gastric mucous membrane easy, that definite evidence as to the real condition of the mucous membrane in these cases has been obtained. The lessons to be learnt from the account of the inspection of the interior of the stomach of Alexis St. Martin in varying conditions seem to have been almost forgotten.

The mucous membrane of the stomach after death is absolutely different in appearance, texture, thickness, and vascularity from what it is during life. During fasting again it is quite different from what it is during active digestion; and as may be imagined, if the bounds of physiological action are passed, and the mucous membrane is being spurred on with pathological energy, the difference is greater still. The vascular and other changes are carried much farther. The mucous membrane is swollen and congested to the utmost, especially in those parts where it is thickest, softest, and most vascular, and where the lymphatic follicles are largest and most numerous. It bleeds with the slightest touch and the blood pours from it. Hæmorrhages seem to break out everywhere in its substance. Its surface is so soft and tender that the slightest irritation causes it to give way. Erosions, which if circumstances are favourable, develop into ulcers, make their appearance wherever it is touched or squeezed by the powerful muscles that surround it; and when it becomes inflamed, as it always does around an ulcer or an abrasion, these consequences are carried farther still. The wonder in such cases is not that hæmorrhages and ulcers occur, but that the stomach and duodenum are ever free from them.

This extreme degree of congestion and œdema of the mucous membrane, which precedes ulceration and often leads to it, is the real cause of the trouble. It is this that in a large proportion of cases is responsible for the symptoms for which ulceration, whether present or not, so often gets the blame. Hæmatemesis, for example, is regarded by many as more or less evidence of the presence of an ulcer, but in all probability it is caused as frequently by minute lesions in the intensely congested mucous membrane as by the giving way of an artery on the floor of an ulcer. I admit that nothing is more easy than to overlook post mortem an opening in a gastric artery. I have myself drawn attention to this. The bleeding has ceased. The artery has contracted so that the opening is apparently closed; and even when the vessels have been injected and the stomach has been excised, so that it can be held up to the light for examination, the source of the hæmorrhage may be almost impossible to detect. But there are too many cases on record now in which thoroughly experienced observers have failed to find an opening in an artery for it to be doubted any longer that hæmorrhage sufficiently severe to lead to hæmatemesis may occur without one. Many times, too, when operating in cases of acute recent hæmatemesis, I have found that the bleeding points were multiple and scattered more or less all over the interior. And I have often been struck by the extraordinary way in which the bleeding in these cases so frequently ceases immediately after the operation without any vessel being tied, though it had been going on daily and almost hourly for weeks before. The fall of the blood pressure, consequent upon the shock of the operation, would account for this at once, if the oozing came merely from congested capillaries. It would have only a short-lived influence if there were an opening in the wall of an artery.

The same thing is true of the pain which is so often looked upon as characteristic of gastric ulcer, because it ceases at once as soon as the stomach is emptied. This, like hæmatemesis, owes its origin far more often to the general morbid condition of the mucous membrane than to the presence of a gastric ulcer, though this undoubtedly makes it worse by the inflammation it sets up in all the parts around. Contact of the acid contents of the stomach with sensory nerves exposed on the floor of the ulcer, the cause that is usually assigned, is certainly not the reason, for there are no sensory nerves there, and the pain may be equally severe when there is no ulcer at all. The immediate source of the pain (until the peritoneum becomes involved) is the spasmodic cramp of the muscles around the antrum and the pylorus; and this is started by the extreme sensitiveness of the mucous membrane, intensified by inflammation spreading from the erosions and abrasions that are so often present. The character of the pain, its severity, the way in which it comes on, the way it ceases, the bursting feeling of distension of which patients complain, the tenderness it leaves behind it, its locality, and, above all, the hardening of the pylorus coincident with the onset of the pain which Moynihan has described in cases in which the operation was performed under local anæsthesia, all bear out this view, until, that is to say, the peritoneum becomes involved in the inflammation and an additional factor is introduced.

In short, it is not the ulcer that is the cause of the symptoms so much as the exquisitely hypersensitive and hyperæmic condition of the mucous membrane, intensified by the inflammation that always complicates it sooner or later. Pylorospasm with the consequences it entails, retention of hydrochloric acid (the so-called hyperchlorhydria) and impaired motility, excessive secretion, hæmorrhages, erosions, and in many instances (perhaps with the aid of some trivial local cause) ulcers are all due to it. It is true that when these consequences follow they combine to make all the symptoms infinitely worse and perpetuate them in a kind of vicious circle; but the essential feature is the morbid hyperæmia of the mucous membrane which disappears almost entirely with the life of the patient and the cessation of the circulation, leaving behind it merely a few traces to show what it has been.

General septic poisoning.—The causes that give rise to this condition of the mucous membrane are the real causes of gastric ulcer. By far the most important and the most frequent is septic poisoning. In its acute form this has long been recognised. There is not a death that occurs from acute septic disease in which intense congestion of the mucous membrane of the stomach, often ending in capillary hæmorrhage, is not a prominent feature. In cases with septic symptoms of less severity it has not attracted so much attention, but recently many instances of appendicitis and of similar affections have been recorded in which hæmatemesis has occurred in what has been supposed to be an inexplicable and an extraordinary manner. In some of these an ulcer has been present, but in the majority nothing of the kind has

been found; and it is open to question whether, when there is an ulcer, this was the source of the hæmorrhage or whether it did not result from capillary oozing due to intense congestion. It is significant that in several instances in which coffee-ground vomiting has been present after septic operations for appendicitis I have found it cease abruptly when the poison had been sufficiently diluted by profuse saline infusion into the tissues.

Local septic poisoning.—The effect upon the gastric mucous membrane is the same when the septic poison, instead of being generated in some distant part of the body and carried to the stomach by the circulation, is swallowed in repeated minute doses. I am convinced that the real cause of the vomiting and hæmatemesis which occur so frequently in young women is poisoning of the mucous membrane of the stomach, caused by the persistent swallowing of septic toxins manufactured in the mouth and throat. The organisms themselves may be killed by the hydrochloric acid, which in these cases is often in excess owing to the spasmodic contraction of the pylorus, but the toxins are not. For a long time past I have made a point of investigating the condition of the teeth in these patients, and in the majority it is simply indescribable. I am convinced that the septic poison which is constantly being absorbed by the mucous membrane of the stomach is not only a powerful cause of the chronic ill-health and anæmia from which these patients suffer, but of the hyperæmia which so often ends in hæmatemesis (the gastrostaxis of Hale White), the enlargement of the lymphatic follicles, the small, round-celled infiltration of the mucous membrane, the erosions which are so common, and the ulcers which are so easily produced in these circumstances by some trivial local cause. Time after time have I seen the drastic remedy of clearing out all the decayed stumps followed by the disappearance of the anæmia and of the symptoms of gastritis with a rapidity which could not be accounted for by the effect of improvement in the power of mastication.

This is the explanation of the well-known fact that while "gastric ulcer" is exceedingly common in this class of patient duodenal ulcer is very rare. The action of the septic poison which is swallowed is local only; it only affects the stomach, not the duodenum. On the other hand, when the septic poison acts through the medium of the circulation, it affects both stomach and duodenum, for the duodenum (so far as its first part, at any rate, is concerned) is in far closer sympathy, genetically and pathologically, with the stomach than it is with the rest of the intestine.

In many of these instances, especially those which occur in young women, the effect of this chronic septic poisoning is intensified by the habit so many of them have of swallowing quantities of vinegar. Information with regard to this is very difficult to obtain, and is never volunteered. It has to be drawn out bit by bit, but I have met with many instances in which a pint a day has been consumed, and a few in which the quantity was occasionally much larger. The effect is probably greater because it is often taken between meals, on an empty stomach, under the curious impression that it will improve the complexion.

The action upon the gastric cells.—Whether septic poisons act in this way only, by causing intense congestion, or whether they may not have in addition a definite devitalising effect upon the cells of the gastric mucous membrane, is a question that cannot be answered yet. Dr. Bolton[2] has brought forward evidence that the latter at least is possible. He has shown that by injecting into the peritoneal cavity certain substances known as gastrotoxins lesions can be produced, limited to the stomach, consisting of blackened patches of necrosis in the mucous membrane, sharply defined and of variable size. These when they disappear leave sharply punched-out ulcers extending from the surface of the mucous membrane to variable depths. And he has proved that these lesions are caused, not by any destructive action on the capillary wall, but by the direct action of the poison on the gastric cells. It is not the result of the removal of any specific resisting power the cells possess: they are damaged, or in some way devitalised, and as a consequence undergo necrosis, disappear, and leave an ulcer indistinguishable from an ordinary acute gastric ulcer. Dr. Bolton has shown, too, that many other toxins possess the same power in a less degree; and he points out that it raises the question whether there may not be endogenous as well as exogenous poisons, which by their action on the gastric cells may produce this result.

Probably there are many other substances that are swallowed which act in the same way, only because they are not swallowed so constantly and persistently as these septic toxins are, every day and every minute in the day, their effect is not so apparent. Alcohol at once suggests itself, especially in the form of new and raw spirit taken upon an empty stomach. It is difficult not to associate the greater prevalence of gastric, and especially of duodenal, ulcer in the male sex after 30 years of age with the consumption of alcohol, particularly in this form.

Other Indirect Causes.

But septic poisons and substances which are swallowed are not the only causes that lead to congestion and impaired vitality. Everything that leads to continued irritation, foods of any kind that disagree or interfere with the work of the stomach, irregularity of meals, overloading the stomach after a period of comparative deprivation, are certainly contributory agents. Exposure to cold is enough in the case of many people, and in many more acts as a powerful accessory cause. The relation between cold and the recurrence of symptoms of gastric and duodenal ulcer after a respite of even many years has often been remarked, and is to be explained not by recurrence of the ulcer, nor by its persistence through the intermediate period, without manifesting its presence in any way, but by a return of that morbid condition of the mucous membrane, due to exposure, which so often ends in ulcer. A condition closely resembling this has been described in connexion with gall-stones, especially one large single one in the gall-bladder (Fenwick); chronic inflammation of the appendix (Moynihan and Paterson), in which the congestion has been sometimes so intense as to end in hæmatemesis; chronic gastric or duodenal ulcer, which though itself a consequence, is no less capable of acting as a cause; and pyloro-spasm, which often behaves in the same way. All of these are known to have been associated with this intensely sensitive and hyperæmic condition of the mucous membrane as causes; and I have myself met with two instances in which I believe it to have been dependent upon the presence of a moveable kidney, for all the symptoms disappeared as soon as this was fixed. Whatever may be the pathological connexion, there can be no question that this condition of intense hyperæmia and hyperæsthesia of the gastric mucous membrane, which hitherto, before the use of the gastroscope, was only a matter of inference, is a very real fact; and that it is the essential cause not only of most of the symptoms which are often attributed to gastric and duodenal ulcer, but, aided, perhaps, by some trivial local cause, in many instances of the ulcers themselves.

The effect of inflammation.—The inflammation that so often occurs in these cases plays a much more important part than is usually believed. It is scarcely ever wanting. The mucous membrane is so soft and vascular that the lightest touch is sufficient to make it bleed, even the pressure of the muscles around it; and if there is the least abrasion it becomes irritated at once by the gastric juice, so that inflammation follows. Only those ulcers show no trace of inflammation in which the death of the tissues is so rapid that there is no time for it to occur. The microscopic appearances show this unmistakably. In cases of acute gastric ulcer there is evidence of past congestion all over the interior of the stomach, especially along the lesser curvature and near the pylorus where the lymphoid tissue is thickest and most vascular. But in the immediate neighbourhood of the ulcer the changes are much more conspicuous. There are minute hæmorrhages everywhere around. All the interstices between the peptic glands and at their base are filled with a round-celled exudation. The lymphoid follicles are enlarged and swollen. Many of them are on the point of giving way. Sometimes they have burst already into the stomach, or through the basement membrane. Everywhere around, in short, there is the microscopic appearance of acute inflammation of the mucous membrane, fading away the farther the part examined is from the ulcer.

Unless there is some definite local cause, such as injury, the actual starting-point of an acute gastric ulcer is nearly always one of these enormously enlarged and inflamed lymphoid follicles. From their texture alone they would be

[2] Proceedings of the Royal Society of Medicine, 1909.

more likely to give way than any other part. As Miller has shown, they hardly exist at birth and do not attain any size until four years of age. From that time through adult life, until late middle age, they are present in abundance chiefly along the lesser curvature and near the pylorus, and there, too, they are larger than they are elsewhere. Wherever there is any irritation, such, for example, as is caused by the continued swallowing of minute doses of septic poisons, they increase in size until they may project far above the surface and become softer and more vascular. Then, if there is the least strain they give way. They are the most vulnerable points, and in them and immediately around them all the inflammatory changes are most obvious.

The same thing is true when the ulceration is chronic, instead of being acute, only then the appearances presented by the mucous membrane have undergone a further change. The lymphoid follicles are still enlarged, and there is still the same small, round-celled infiltration of the interstices in the mucous and submucous layers, but in addition there are thickening and condensation of all the fibrous tissue. The basement membrane is denser and more fibrous. The strands passing from it have lost their delicate character. The adventitia of the vessels is thickened. Sometimes there is thickening of the other coats as well. Everywhere there are stiffening and loss of mobility of the mucous membrane, and a disproportionate development of the lymphoid tissue. Everywhere, as Miller has shown, when there is a chronic ulcer, there are around it and over the rest of the mucous surface all the ordinary features of chronic inflammation, with here and there alterations in the walls of the blood-vessels, and, most important of all, with other chronic ulcers in the process of making.

The effect of hydrochloric acid.—Another point in the question of the causation of gastric and duodenal ulcers that is of considerable importance is the relation between them and the hydrochloric acid of the gastric juice. That ulcers are in a way dependent upon the presence of the acid is obvious, for they only occur in those parts of the mucous membrane that come into contact with it. It is therefore an essential factor in their production. Its assistance is needed for the digestion and removal of the tissues in the area that has been injured. But the strongest hydrochloric acid that is found in the human stomach is not capable by itself of causing an ulcer except under very special conditions. The action of the acid is probably best shown in such simple straightforward examples as the formation of a jejunal ulcer after gastro-enterostomy (Paterson) undoubtedly from auto-digestion; and the way in which an excess of acid helps gastrotoxins injected experimentally into the peritoneal cavity in causing the death and subsequent digestion of portions of the gastric mucous membrane (Bolton). Such instances as these, which are supported by numbers of other experiments, prove that hydrochloric acid, especially when in excess, lowers the vitality of, even if it does not directly kill, tissues which are not naturally immune or which have been injured, and ensures their digestion. They do not prove that hydrochloric acid, even when it is in excess, has any effect upon an uninjured gastric mucous membrane.

So far as clinical cases of gastric ulcer are concerned, it is well known that acid of much greater strength than is ever secreted by the gastric mucous membrane may be swallowed with impunity and without causing pain, even when an ulcer is present already; and while in many cases of ulcer hydrochloric acid appears to be in excess, this is certainly not so with all. There are many instances in which there is a decided deficiency. As a matter of fact, the excess of free hydrochloric acid, the so-called hyperchlorhydria, to which so much importance has been attached, is a secondary consequence of spasmodic contraction of the pylorus, or of hypersecretion of gastric juice, or of both together; and these are the result of the morbid condition of the mucous membrane induced by such causes as chronic septic poisoning or irritation spreading from an ulcer. The excess is due to accumulation in the stomach. There is nothing whatever to show that the strength of hydrochloric acid in gastric juice as secreted is ever raised in any way, though it may be lowered. So long as the epithelial lining of the stomach remains intact and uninjured hydrochloric acid in any strength that can be secreted has no effect. But if from any cause, whether it is the cause that gave rise to the pylorospasm and hypersecretion or any other, the protecting epithelial layer of the stomach is injured or the deeper tissues exposed, the acid at once comes into play; the injured tissues are injured further still; inflammation sets in; the débris is digested, and an ulcer left. Ulceration does not occur except where hydrochloric acid is present, for digestion does not; but hydrochloric acid, whether it has accumulated so as to be in excess or whether it has not, cannot cause an ulcer unless there is some other agent at work to initiate the lesion. Given this other agent the effect of the acid, as Bolton has shown, is in proportion to its strength.

Wimpole-street, W.

THE PHYSIQUE OF THE PHTHISICAL.

BY H. DE C. WOODCOCK, M.R.C.S. ENG., D.P.H.,
HONORARY PHYSICIAN TO THE TUBERCULOSIS HOSPITAL, LEEDS.

§ 1. THE tables appended to this article are in part the result of study in morbidity rather than in mortality among phthisical subjects. No notice has been taken in them of the ordinary and universally recognised physical signs of phthisis, such as ratio of depth of chest to width, presence of wing-like scapulæ, &c.; but an attempt has been made to call attention to certain other appearances coincident with phthisis, though not generally recognised, and to record somewhat fragmentary details rather than to build upon them. The figures here given have been verified by wide investigation since the tables were made; an immense number of cases not included in the tables have been examined in all classes except in No. 6 of Table I., the New York Life Assurance cases.

§ 2. There are one or two points to which it may be well to call special attention. First, and most important of all, there is the peculiar appearance of the soft palate, which I begin to look for with certainty in almost all cases o marked phthisis. The phthisical soft palate is of a pearly bluish-white tint, and is covered with a somewhat mucoid moisture. It certainly differs from the chlorotic palate. I place it as a sign of sinister import equal to the rapid phthisical pulse, or the temperature, pulse, and respiration reaction to fatigue.

§ 3. This fatigue reaction is worth referring to. The morning is the best time to commence the observation. The fatigue causes a rapid rise in temperature, followed by a slow descent lasting until, and merging in, the usual evening rise always expected in phthisical patients.

§ 4. The hand ratio is found by comparison of the length of the hand, from the ridge of the ulna in an oblique line to the end of the longest finger, with the breadth across the hand at the knuckles. This measurement is best taken by means of an instrument resembling that used by shoemakers for measuring feet; if a protractor is attached for measuring hyperextension, so much the better. Hyperextension of the fingers on the metacarpals or of the terminal on the penultimate phalanx is a sign commonly found in the cases of people in advanced or rapidly advancing phthisis. Doubtless other forms of hyperextension would show a similar condition. Much still remains to be done in this direction—for instance, in comparing the length of the phalanges with that of the rest of the hand. In the case of patients who have done much manual work hyperextension may be less than it would naturally be; and again in other cases, as, for instance, in violinists, it may be greater.

§ 5. Reference is made in No. 5 of Table I. to the clubbing and curving of the ends of the fingers. As the two conditions of phthisis and bronchiectasis so frequently coexist, it is not surprising that marked clubbing of finger-ends should often be seen at Armley. Moderate clubbing is frequently found where the signs are those of phthisis and not of bronchiectasis. Hence, clubbing as a means of diagnosis has in my opinion lost some of its value.

§ 6. Philip's glands—i.e., the enlarged deep glands just above the clavicle—are always found in phthisical children; but their presence does not necessarily indicate phthisis, since they are so frequently met with in apparently normal children. In the same way, enlargement of the other glands of the neck is so generally found in all classes of patients who consult the doctor for any and every illness that even if one found them in every phthisical patient the diagnostic

TABLE I.—*Men.*

Number.	Designation.	Number of cases.	Age.	Height.	Chest.	Ratio of chest to height.	Weight (1).	Hand ratio.	Hyper-extension.	Hard palate (2).	Soft palate.	Philip's glands.	Other glands of neck.	Teeth	Skin conditions.	Alimentary conditions.	Other notes.
			Years	ins.	ins.		lb.										
1	West Riding artisans, presumably healthy, members of one club, of 25 different trades.	80	20–40	65·58	39·9	0·562	152·5	—	—	30% defective.	—	—	—	70% defective.	Acne common.	—	Continental statistics show a greater height.
2	Jew artisans, presumably healthy, members of two clubs, mostly tailors—																
	(*a*) British born.	40	20–40	67·1	35·56	0·53	157·0	—	—	20% defective.	—	—	—	10% defective.	,,	Constipation very common.	The Jew has large nostrils, but the turbinates often trouble him, and operation on account of hypertrophy is frequent.
	(*b*) Foreign born.	40	20–40	66·8	36·6	0·55	159·5	—	—	22·5% defective.	—	—	—	20% defective.	,,	Constipation exceedingly common; dilatation of stomach rather common.	
3	Phthisicals (not advanced) at Gateforth Sanatorium.	150	20–40	65·2	32·8	0·503	133·3	0·5	Not present.	60% defective.	Normal.	Not found in the majority of cases.		90% defective.	Acne seldom present.	—	80% showed some nasal deformity.
4	Later cases at Gateforth of the same type.	—	20–40	67·0	32·9	0·491	133·4	0·49	20% marked.	—	20% showed marked pallor.	—	—	80% defective.	A few cases of acne and of tinea versicolor.	—	—
5	Advanced phthisicals at Armley Hospital.	20	20–40	65·6	32·0	0·487	115·5	0·45	Present in most cases.	In most cases higher than the average.	Anæmic in most cases.	Can be felt in most cases, but not markedly enlarged.	It is the exception to find any marked enlargement.	(*a*) Fine, handsome, but delicate teeth, not heavy, often seen in rapidly developing cases of very acute phthisis. (*b*) Badly decayed teeth in the majority of cases. (*c*) Strong, broad, coarse teeth, going with stumpy hand; always a sign of resistant type, often associated with clubbed finger-ends (4).	Acne seldom present. Pityriasis versicolor exceedingly common.	Dilatation of stomach quite common (5).	Average temperature at 4 P.M. 101°. Average pulse 96.
		10	20–40	65·0	33·0	0·49	123·5 (3)	0·55									
6	New York Life Assurance cases—

REMARKS.—*No. 1:* 23½% have physical signs compatible with phthisis. Localised percussion dulness apical and Grancher's signs. None had enlarged tonsils, some had abnormal palates; error from nasal intonation was possible. In nearly all cases there was intermittent febrility in personal history. Below average in height, weight, and chest measurement. Most had some defect of palate and bad teeth. *No. 2:* 2·5% have rickets. Localised pulmonary signs in 12·5%. Two gave Still's sign of mediastinal gland enlargement. *No. 3:* Four cases with doubtful signs; one of undoubted phthisis; in all 8·4%. Nostrils much larger than in English. No marked case of rickets. *No. 4:* Rickets is commoner than with Jews, but less common than with English. Signs of phthisis common; several cases are under treatment at Leeds General Infirmary. Afebrile bronchitis is common among Irish children. *No. 6:* Hand ratio 0·45. Hyper-extension slight in 45 %; marked in 35%.

value would not be great. If, for instance, a patient came to me with marked physical signs localised, with round palate and good teeth but *with anæmic soft palate and no enlarged glands*, I should have the fear, even if he had gained weight and improved, that the case might go rapidly wrong at any time. This is, of course, equivalent to saying that absence of enlarged glands helps me in some degree to an adverse prognosis.

§ 7. With regard to skin conditions of phthisicals, I can recall only one case of lupus in ten years among the patients under my care at Armley and Gateforth for pulmonary tuberculosis. Tinea versicolor is especially common at Armley Hospital, which harbours advanced cases, and not common at Gateforth, where only early cases are received. Marked acne is not common; indeed, it is hardly ever found among advanced phthisicals.

§ 8. Several of my phthisical patients with dilatation of the stomach were seen by Mr. B. G. A. Moynihan, who has helped me to the conclusion that this form of atony is of common occurrence among tubercular patients.

§ 9. In a footnote to No. 5 of Table I. I have referred to athletes. We have several in our wards, as well as soldiers, sailors, returned emigrants, and others who might be classed under the general name of "wanderers." It is impossible to shut one's eyes to the fact of their number, and I note that the United States returns (Osler, Rogers) give figures agreeing with this. Thus, mortality from phthisis in the United States is for native-born whites 155·4 per 100,000; among foreign-born whites it reaches the figure of 231·1 per 100,000, In Ireland the mortality from phthisis is 258 per 100,000; among recently immigrated Irish in the United States it amounts to 339·6 per 100,000. It must be borne in mind that few patients who die with pulmonary tuberculosis die from pulmonary tuberculosis; the cause of death is generally a mixed infection. Sooner or later everyone has pulmonary tuberculosis, but only a small minority die from it.

§ 10. In spite of the good figures obtained for Jewish artisans (see No. 2 of Table I.) I have not found Jewish physicians in Leeds enthusiastically impressed with the physical superiority of their people. The Jews descend a pathological incline of their own. They suffer very much, especially in Leeds, from

TABLE III.—*Comparison of Conditions in Phthisical and Non-Phthisical Children.*

—	Age.	Height.	Chest.	Ratio of chest to height.	Weight.	Hand ratio.	Hyperextension.	Hard palate.	Soft palate.	Philip's glands.	Other glands of neck.	Tonsils.	Adenoids.	Remarks.
English boys—		ins.	ins.		lb.									
Average	12–13	61	27	0·44	69	No difference.	—	No conclusions formed.		—	—	—	—	—
Phthisical	12–13	57	25	0·44	62		—			—	—	33½% enlarged.	—	These were children with no ordinary clinical picture of phthisis.
Jewish boys—														
Average	12¾	56	25	0·45	84	No difference.	—	No conclusions formed.		—	—	No conclusions formed.		—
Phthisical	12¾	56	24	0·43	75		—			—	—			See note above. Signs indicative of phthisis were: Grancher's signs, Philip's glands, percussion apical dulness, occasionally basal dulness.
Girls: Rapid cases of phthisis with marked signs.	About and after puberty	Varied.	Below average	—	Much below average	—	Generally present.	High, round.	Anæmic	—	—	No enlargement as a rule.	Not present	Family history generally bad; among these are four girls from one family.

TABLE IV.—*Comparison of Resistant and Non-Resistant Types among Phthisicals.*

Phthisis type.	Age.	Height to weight.	Chest to height.	Hand.		Palate.		Enlarged glands of neck.	Tonsils.	Nose.	Pulse.	Temperature.	Skin conditions.
				Width to length.	Hyper-extension.	Hard.	Soft.						
Resistant.	—	Low ratio.	High ratio.	High ratio.	Absent.	*Round*, with heavy teeth, or *irregular*, with bad teeth.	Red.	Present.	Enlarged tonsils are more often found in the resistant than in the non-resistant type.	Large.	Slow.	Generally low.	Acne if present is of good prognosis.
Non-resistant.	Puberty to 25 years showed most acute cases.	High ratio.	Low ratio.	Low ratio.	Present.	*Round*, with light fine teeth, not decayed, or *narrow*, with bad teeth.	Finely tinted, nearly white.	Generally not prominently present.	—	Narrow nostrils.	Quick.	Low or high; not indicative. See §3.

diseases of nervous origin, such as epilepsy, diabetes, &c. The tendency, also, is to tubercular morbidity, not to mortality. The Jews who have died in our hospitals at Gateforth and Armley have generally died with symptoms of meningitis. Among Jewesses I have found a frequent condition of floating kidney.

§ 11.—Cases of hæmoptysis form a class by themselves independent of physique. Many such cases are found among tall, fine, apparently robust men. I have with the matrons of Gateforth and Armley run over the list of deaths from sudden hæmoptysis; most of the men were above the average in height and in most cases above the average in weight. We have had few cases among women. To increase weight rapidly is to increase any present liability to hæmoptysis. (See No. 6 (*a*.) of Table I.)

§ 12.—With regard to the frequency of phthisis in young subjects, it may be pointed out that in Ireland phthisis does not account for such a number of deaths at an early age as in England and Scotland. Sir John Byers states that the highest death-rates in Ireland are between 15 and 45 years. He found that in 1906 there were in that country 152 deaths from phthisis of children under 5 years of age, 140 of children from 5 to 10 years, and 367 of children from 10 to 15 years. In Scotland Philip records the following deaths from phthisis among children [1]:—

Age.	Under 1 year.	1–4 years.	5–9 years.	10–14 years.
Number of deaths ...	50	175	150	294
Rate per 100,000 ...	4·2	4·1	3·0	6·2

Cummins remarks: "The mortality in the United States and in Great Britain, highest in the first year, sinks rapidly through childhood to rise after puberty." Philip's figures show a rise before puberty.

Leeds.

A SYMPTOM-COMPLEX IN RUPTURED ABDOMINAL HYDATID.

BY J. E. BARLING, M.B., CH.M. SYD.,
AND
D. A. WELSH, M.A., M.D. EDIN.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF SYDNEY.

(*From the Laboratories of Pathology in the University of Sydney.*)

THE facts here presented have reference to a series of six cases of hydatid disease complicated by rupture or leakage of the cyst into the peritoneal cavity. In five of the cases the cyst was situated in the liver, in the remaining one in the spleen. The cases all occurred within a period of 18 months. The symptom-complex to which we would draw attention includes (1) eosinophilia, (2) peritonitis with effusion, and (3) urticaria.

1. *Eosinophilia.*—In our paper on the leucocytosis of hydatid disease [2] we showed that eosinophilia is by no means an invariable accompaniment of hydatid infection in the human subject. As a matter of fact we found that in 50 per cent. of the cases examined the blood change was a marked one, in another 25 per cent. the change was moderate, whilst in the remaining 25 per cent. it was entirely absent or so slight that it was of no use from a diagnostic point of view.

But so far as our present experience goes, we have found eosinophilia to be a marked feature of every case in which the cyst has ruptured or leaked into the abdominal cavity. This is, of course, precisely in accordance with what one would expect.

The number of eosinophiles present in the blood in the six cases varied considerably. In three of them the reaction was excessive, the actual figures being in the first case 8580 eosinophiles per cubic millimetre, or a number equal to 54 per cent. of the leucocyte content of the blood; in the second case 8200 eosinophiles per cubic millimetre, or a number equal to 47 per cent. of the leucocytes; and in the third case 5440 eosinophiles per cubic millimetre, or a number equal to 34 per cent. of the total leucocytes.

In two of the remaining cases the blood change was a marked one, there being in one of them 1628 eosinophiles per cubic millimetre, a number equal to 22 per cent. of the total leucocytes, and in the other 1320 eosinophiles per cubic millimetre, a number equal to 12 per cent. of the leucocytes present.

In the one remaining case the reaction, though slight, was definite, there being 354 eosinophiles per cubic millimetre, a number equal to 5·6 per cent. of the total leucocytes.

2. *Peritonitis with effusion.*—The second outstanding feature of these cases of ruptured abdominal hydatid is the peritonitis set up by the presence of the hydatid material in the peritoneal sac. The hydatid contents would seem to be very irritating to the peritoneum, so that whether the rupture be small, resulting only in the escape of a small amount of material, or whether the rupture be large, resulting in the escape of the whole cyst and its contents, an intense reaction on the part of the peritoneum is set up. The most noticeable feature of this peritonitis is the large amount of fluid poured forth. In two of the cases, where a periodic leakage had taken place, the most marked clinical feature was the large amount of fluid in the abdominal cavity, suggesting tubercular peritonitis. In one of these cases the history of abdominal swelling dated back for nearly three years; in the other for two months.

In two of the cases in which the rupture had been followed by the sudden projection of the whole of the contents of the cyst into the abdominal cavity, and in which some time had elapsed between rupture and operation, the omentum was found spread out over the intestines, having become converted into a thickened gelatinous membrane. In this way a sac had been formed between the anterior abdominal wall and the altered omentum, which contained bile-stained fluid, shreds of lymph, and broken-down hydatid membrane, whilst the remains of the cyst in the liver were becoming shut off by thick, fleshy adhesions.

3. *Urticaria.*—The third feature is the urticaria which attends the rupture of the hydatid cyst. The association between ruptured hydatid cyst and urticaria has long been recognised and is referred to as a sign of importance.

In the cases which have come under our observation it has not been invariably noticed. In two of the six cases no history of a rash could be obtained, although careful inquiries were made on this point. In the other four cases urticarial rashes were noticed by the patients, coming on soon after the rupture, lasting for a day or two, and then passing off. In one case there was a history of recurring attacks of urticaria, the attacks in all probability coinciding with a periodic escape of hydatid fluid into the abdominal cavity.

In reviewing the results of our examination of the leucocyte reaction in hydatid disease, we thought that these six cases of ruptured abdominal hydatid were of sufficient interest and importance to warrant us in placing them on record. We think, too, that we are justified in saying that the condition has a very definite and distinctive symptom-complex, the main points to be relied upon in coming to a diagnosis being (1) the eosinophilia, (2) the presence of free fluid in the abdominal cavity, and (3) the appearance of urticaria. Of these three phenomena the blood reaction and the peritoneal reaction are the most constant. Urticaria, also, is probably a constant phenomenon, but may pass unnoticed by the patient. In addition, we would point out that the presence or absence of eosinophilia is a matter of considerable importance in the differential diagnosis of certain cases where free fluid in the abdominal cavity is the most salient clinical feature.

We beg to thank the honorary and resident staff of the Royal Prince Alfred Hospital for their kind assistance.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—As the result of the examinations for entrance scholarships held on Sept. 19th, 20th, and 21st, the following awards have been made:—University Scholarships: 50 guineas, M. O. Raven, Trinity College, Oxford. Scholarship of 50 guineas divided: J. P. Davies, University College, Cardiff; and W. H. Edmunds, University College, Cardiff; bracketed equal. Open scholarships in Natural Science: £145, D. Menzies; £25, H. B. Taylor, St. Paul's. Epsom Scholarship (by nomination): R. M. Handfield-Jones.

CLINICAL SURGERY IN JAPAN.

BY YOSHIHIRO TAKAKI, M.R.C.S. ENG.,
PROFESSOR OF SURGERY, TOKYO CHARITY HOSPITAL MEDICAL COLLEGE.

(*Concluded from p. 933.*)

IV.—ACUTE APPENDICITIS.

IN this paper it is not my purpose to discuss the whole aspect of appendicitis, but from my experiences during the last four years (1906–10) I should like to call attention to the clinical aspects—especially the danger signs in the early stage and also the treatment of the acute cases.

15 other cases of acute or subacute appendicitis (9 males; 6 females total, 105 cases.

CASE 1.—A business man, aged 25 years, was admitted on Dec. 16th, 1906, and was discharged on Feb. 16th, 1907. Previous history.—Had suffered from typhoid fever in China in 1904. Present history.—He had a sudden pain in the lower abdomen on Dec. 14th. This was followed by general enlargement of abdomen with fever. On admission facies abdominalis was typical. The abdomen was generally distended, and the resistance was strong. The patient could not bear to be touched in the lower abdomen owing to pain. No action of bowels. Vomiting present, mostly bile. Tongue covered with white fur. There was loss of appetite. Temperature 36·2° C. Pulse 130, small, weak. Treatment.—Immediate laparotomy was performed. Two incisions were made—one in the mid-line and the other in the semilunar line. The appendix was swollen and red, almost gangrenous. There was a small perforation at its root. It was excised, and the stump was closed. The cavity was washed clean with normal saline solution owing to the extensive peritonitis, and the operation was finished by closing the mid-line incision and leaving the other open. The patient developed acute dilatation of the stomach a few days after the operation, and brought up a large quantity of greenish fluid several times. A stomach bougie was passed and the stomach was washed out several times. The patient, in spite of this complication, was completely cured.

CASE 2.—The patient, a female, aged 53 years, was admitted on Dec. 18th, 1906, and was discharged on Jan. 20th, 1907. Previous history.—She had suffered from general œdema at the age of 38 years and was cured in 50 days. About Jan. 5th, 1906, she had had a painful tumour in the appendix region without rigor, high fever, or vomiting She never left her work and got well in 10 days. Again the same painful tumour appeared in the middle of July and disappeared in 12 days. Present history.—On Nov. 25th it appeared again. The pain had been getting severe with increase in the size of the tumour. From about the 15th the fever became high and the tumour seemed to be getting softer. On admission the patient was somewhat anæmic and her appetite was diminishing. There was neither nausea nor vomiting. The bowels were constipated. There was a tumour extending from just above Poupart's ligament and the symphysis pubis below to the umbilicus above. It was limited by the anterior superior iliac spine outside and the linea alba on the inner side. The central portion was red and fluctuating. It was hot and tender and measured 9 centimetres long and 10 centimetres across. The hip was slightly flexed. The temperature was 37·6° C. and the pulse was 119. Immediate operation was proceeded with. The abscess contained a large quantity of greenish-yellow fæcal pus and turned out to be an appendix abscess breaking through a small hole in the abdominal wall into the subcutaneous tissues.

CASE 3.—The patient, a male, 35 years of age, was admitted on Feb. 16th, 1909, and was discharged on May 15th. Previous history.—During the previous four years he had had several acute attacks of appendicitis. Present history.—On Jan. 26th, 1909, he had slight lumbar pain, which got well in a week. On Feb. 7th the pain reappeared with rigor and fever. Besides there was noticed some dilatation of the appendicular region and the right flank. The pain became more severe and the patient came to the hospital. On admission he was found to be generally run down and anæmic. The abdomen was dilated on the right side, especially from the flank to behind more than in front. The swelling was tender, soft, and fluctuating. The temperature was 37·5° C. and the pulse was 104. The patient was immediately operated upon, an enormous quantity of fæcal, gaseous, yellow pus mixed with blood clot being let out through two incisions, one in front and one at the back. The appendix was not seen. Complete cure resulted after 91 days.

CASE 4.—The patient, a medical student, aged 23 years, was admitted on Nov. 29th, 1907, and was discharged on Jan. 25th, 1908. The previous history of the case was one of pleurisy, malaria, beri-beri, &c. Present history.—The illness had commenced with sudden fever and pain on Nov. 20th. There was also vomiting. The patient becoming worse he came to the hospital. On admission the abdomen was found to be generally distended and resistant. The appendix region was prominent and very tender. Fluctuation was felt. The skin was hypersensitive. The temperature was 39° C. and the pulse was 95. Treatment.—Immediate operation. A large abscess containing a fæcal purulent discharge was discovered. The appendix was nearly four inches long, and was thin, greenish white, and easily tearable. It was seen on opening the peritoneum, and by pulling slightly it came out of the wound without cutting. It contained seven fæcal stones. The wound was left open, gauze packing being employed. Fever persisted for a long time after the operation, but complete cure eventually resulted.

CASE 5.—The patient was a student, aged 24 years. He was admitted to hospital on March 12th, 1908, and was discharged on May 20th. He had had one attack in 1907, and had been treated in this hospital. He had left the hospital with a fæcal fistula on Dec. 6th, and had been attending as an out-patient. Present history.—On March 11th the patient experienced a sudden pain near the old would, and this was followed by rigor and fever with dilatation, so he at once came to the hospital again. On admission there was a large quantity of discharge from the sinus. Around the wound there was some distension and much tenderness. Treatment.—The sinus was enlarged and a fair quantity of pus was let out. It was impossible to find the appendix owing to dense adhesions, and so it was not removed. For a time the patient did well, but the fæcal fistula again opened, and in spite of several small operations it would not close. The patient left the hospital on May 20th Against my advice he underwent an extensive operation for radical cure in another hospital, and he died within 24 hours from diffuse peritonitis.

CASE 6.—The patient, who was 18 years of age, was a geta-maker. He was admitted on June 9th, 1909, and was discharged on July 26th. There was no previous history. Present history.—In the early morning of June 5th he felt a sudden severe pain in the appendix region, which gradually became more severe with the loss of appetite, rigor, and fever. Later there was vomiting with abdominal dilatation. On admission the patient's face wore a painful expression. The abdomen was generally distended and rigid. There was strong resistance with tenderness all over. No tumour was felt in the appendicular region. The temperature was 37·5° C., and the pulse was 102. Treatment.—Immediate operation. There was diffuse peritonitis. A large quantity of greyish-yellow pus was let out. The appendix was gangrenous and perforated. The patient had a suppurative parotitis seven days after operation, and it was opened on the 17th.

CASE 7.—The patient, a medical man, aged 53 years, was admitted on June 19th, 1909. There was no previous history. On June 15th he felt a sudden pain in the lower abdomen. On the next day, feeling a tumour in the appendicular region, he came to the hospital. On admission he was found to be suffering from loss of appetite and general malaise. There was a tender, hard tumour in the appendicular region. The temperature was 38·5° C. and the pulse was 104. Treatment.—The patient was advised to undergo the operation at once, but he being a medical man and feeling better after admission than when at home, unfortunately refused. So I had to treat him with an ice-bag, &c. The swelling seemed to get smaller and he was altogether improving, but on the 20th he got up himself, feeling well, and directly after he complained of very severe pain in the abdomen, with difficulty in breathing. So the operation was done at once. A thin purulent fluid was let out. The appendix, perforated, greyish-white, and gangrenous, was removed. The patient did not improve and he died on the 22nd. The case was one of sudden rupture of an abscess into the peritoneal cavity.

CASE 8.—The patient, who was a military officer, 54 years of age, was admitted on August 27th, 1909. The previous history of the case was one of hæmorrhoids, gonorrhœa, bubo, and epididymitis. Present history.—About a month previously the illness had begun with a sudden pain in the appendicular region and fever. Later a hard lump was felt. Under treatment the patient had been getting gradually better until about a week ago before admission. Since that time occasional rigor and high fever had appeared and he had not been getting worse. On admission the patient presented an anæmic and very much run-down appearance. The abdomen was not enlarged, except near the right costal margin. In the appendicular region there was a small tumour, which was slightly tender and hard. Some tenderness was present in the region of the liver. There were rigor and high temperature at intervals. Treatment.—After a few days' watching, seeing the gradual disappearance of the tumour and the enlargement of the liver, this case was diagnosed as an abscess of the liver secondary to acute appendicitis. So an incision was made through the semilunar line on to the liver, and by probing with a trocar a fairly large abscess was evacuated from the right lobe. Subsequently the temperature went down for a few days, but it rose again with rigor, and a small swelling was noticed over the left lobe. So another incision was made over this under local anæsthesia and the pus was let out. On and off six abscesses were evacuated altogether, but the patient at last succumbed to general weakness. The diagnosis was pyæmic multiple abscesses of the liver.

CASE 9.—The patient, a medical student, 25 years of age, was admitted on July 21st, 1907, and was discharged on Sept. 22nd. No previous history was obtained. Present history.—More than two months previously the illness had commenced with acute abdominal pain, and the patient had entered the Matsuyama Hospital. There his case was diagnosed as peritonitis following acute appendicitis. I was called in for consultation and he was transferred to the Tokyo Hospital. On admission it was found that there was an absence of appetite and the patient was thin and in a weak state. The abdomen was not enlarged, but there was tenderness in the lower abdomen. The bowels were not acting well and recourse was had to the enema. Treatment.—Seeing the very weak condition of the patient the operation was delayed until more general improvement took place. Luckily at the end o that time a large amount of pus was passed in the urine suddenly. The discharge of pus lasted for a week and the urine cleared. The patient showed a rapid improvement after this and was cured without an operation. The pus was probably due to the rupture of an abscess into the bladder.

,, 40 ,, 50 ,,	.....	4·4	,,
,, 50 ,, 60 ,,	.....	4·4	,,

From this table it will be seen that over 90 per cent. of all cases occurred before the age of 40 years. The most frequent time is between 20 and 30 years of age (52·2 per cent.). The youngest was 10 years of age and the oldest 57 years.

Although the lowest age was 10 years in the above table, I have met with one case in which the patient was aged only 3 years and 5 months. It was not described with these cases, as the patient was operated on for the intestinal obstruction. The patient seemed to have suffered from occasional abdominal pain for about four weeks before admission. For the last five days the pain had been frequent and more severe. He had not passed a motion for a week. On admission the abdomen was found to be generally swollen, especially on the right side. He seemed to have frequent pain at intervals. There seemed to be an indefinite tumour in the right iliac fossa. The temperature was low. This case was diagnosed as intussusception, but on opening the abdomen it was found that the intestinal obstruction was due to the inflammatory adhesion of the tip of the appendix to the back of the cæcum. Into the loop formed by the appendix the small intestine slipped and was strangulated. The patient made an uninterrupted recovery.

The disease is most frequent at the most active period of life—the period when persons are liable to various exposures and to indiscretion in taking food. The non-frequency in old age is no doubt due to the gradual atrophy of the appendix, which takes place as age advances. The atrophic changes have been borne out by several well-known reports.

Sex.

Females	20	= 19	per cent.	Total 105.
Males	85	= 80·9	,,	

Percentage of Males.

Sonnenburg	1000	=	67	per cent.
Roux	670	=	53	,,
Deaver	300	=	61	,,

The percentage of my cases is larger than is that of others, but it is probably accounted for by the greater number of acute cases. Out of 105 cases there were only six chronic cases. Of the mild cases not operated on there were 24 cases:—

Female	9	=	37·5	per cent. } Total 24.
Male	15	=	62·5	,, }

Thus among the milder cases the percentage lessens. There is no doubt that the disease more often occurs in males than in females. Whether this is due to the anatomical condition of the blood-supply I cannot say. Perhaps it is partly due to that, but I think mainly to the less exposure to excitement and trauma, and also to less indiscretion in diet. Moreover, the lesser percentage in Japanese females may be accounted for by the less excitable and quieter life led compared with the lives of Europeans or Americans.

Previous History (Acute Cases only).

Of the 77 acute cases operated on the following is the list:—

Nil	47	Diarrhœa (obstinate)	2
One attack	10	Indigestion (habitual)	4
Two attacks	4		—
Several attacks	3	Total	77
Typhoid fever	7		

Etiology (Acute Cases only).

Trauma	2	Those who had some gastric or intestinal trouble	12
Constipation	2	Fæcal stone	10
Indiscretion in food	9	Worm	2
Those who had had attacks before	17		—
		Total	54

Two cases had the distinct history of a blow in the abdomen just before the attack, and in two other cases there was constipation for some time before operation. Nine cases were directly attributed to over-eating just before the attack. In 17 cases there had been a previous attack. In 12 cases the patients had suffered from some gastric or intestinal trouble previously, and in ten cases there had been one or more fæcal stones.

As regards the fæcal stone it seems to act as the cause in a few cases. I had one case in which the inflammation was limited to the tip of the appendix, where a fæcal stone was lodged. But I have seen many cases in which, although the stone was present in the appendix, yet no abnormal symptom showed itself during lifetime.

There is no doubt that the previous attacks and intestinal illnesses often lower the resisting power of the appendix and make it liable to an attack.

The indiscretion in taking food must be counted as one of the chief direct causes. But in the greater number I cannot find any immediate cause.

Twice I have seen a worm in the pus, but whether worms were the cause of the attack I cannot say.

As regards the bacteriological causes, unfortunately I have examined only 10 cases with the following results:—

1 case, bacillus coli.
1 ,, bacillus coli and staphylococcus aureus.
1 ,, ,, ,,
1 ,, ,, ,,
1 ,, bacillus coli and streptococcus pyogenes.
1 ,, bacillus coli.
1 ,, bacillus coli and staphylococcus aureus.
1 ,, ,, ,,
1 ,, bacillus coli.
1 ,, bacillus coli and staphylococcus.

From these it will be seen that the bacillus coli is generally present and that the mixed infection is more frequent. Also the presence of streptococcus is rare. These cases are very few and they must not be taken as definite. I hope to make a further study.

Symptoms and Signs.

1. *Pain.*—The pain is generally severe and commences in the right iliac fossa, but it may be indefinite abdominal pain, or may be felt around the umbilicus, in the epigastrium, or on the left side. I had one case in which the patient complained of pain in the vagina. Another patient complained of pain in the lumbar region at the commencement. The degree of pain varies in different individuals, but generally very severe pain denotes the bad cases. The pain may be continuous or may occur at intervals. The sudden disappearance of pain often means serious trouble with the appendix.

2. *Fever.*—In a few cases the fever does not rise much above the normal, but usually it is high at the commencement of illness and will then become lower in a few days. The continuance of high fever for over five days is not a good sign. The sudden fall of temperature after being high is a dangerous sign and denotes gangrene or perforation of the appendix—that is, if no other improvement is present. In some slight cases the patient's temperature did not rise above the normal.

3. *Rigor.*—This is not always present, but the presence of frequent rigors at the commencement ought to make us think of some serious complication.

4. *Vomiting.*—This also is not always present. Frequent vomiting at the beginning is usually a serious sign, and we must be ready to operate at once.

5. *Diarrhœa and constipation.*—In a few cases there was diarrhœa, but in most cases there was constipation.

6. *Tumour.*—At first the tumour is not felt and the abdominal wall is somewhat rigid over a more extensive area, but usually in a short time a hard tender tumour is felt in the appendix or right iliac region. This is due to inflammatory induration and adhesions. In a few cases the tumour was due to the dilatation of intestine owing to adhesions, but a hard tumour with extreme tenderness and high temperature meant the presence of pus. Of course, there are exceptions, but under those circumstances I have nearly always found pus. When there is fluctuation there cannot be any doubt. The tumour is dull on percussion when near the surface, but is resonant if covered over with intestines. The omentum as the protector of the peritoneal cavity usually forms part of the tumour. Several times I have found the omentum covering the appendix completely. Later, when suppurating, the tumour becomes soft and fluctuating.

7. *Rigidity.*—The abdomen is generally found to be held more rigid than usual. The area is more extensive at the commencement when the inflammation is not localised than at the later stage. This often misleads the inexperienced in diagnosing. Later, when localised the rigidity more or less is limited to the right iliac fossa or over the tumour. The movements of the abdominal wall in respiration are limited according to the extent of the inflammation. In very severe cases the respiration may be wholly thoracic, as in diffuse peritonitis or when the sudden rupture of an abscess takes place.

8. *Frequent micturition.*—In a few cases the patient complained of frequency of micturition. In these cases the appendix was present in the pelvis or the inflammation extended to the bladder.

9. *The flexion of the right leg.*—In diffuse peritonitis the patient usually holds his legs flexed, but in certain cases of acute appendicitis the right leg alone is often kept in that position, and owing to the pain the patient cannot stretch his leg. This was generally due to the presence of an inflamed appendix behind the ilio-psoas muscle.

10. *Hypersensibility of the skin.*—By some this sign is said to be diagnostic of acute appendicitis. The area of hypersensibility is usually extended over the right iliac fossa round the right flank to the lumbar region. Sometimes it may be beyond the linea alba to the left side. Even the lightest touch causes pain. It is said to be characteristic of this disease, and by this we can diagnose it from other inflammatory abdominal diseases. I have found this sign in a few cases, but not always.

11. *Rovsing's sign.*—This sign was only obtained in a few cases. Of course, in some cases it was very difficult to ascertain it owing to the tenderness.

12. *Leucocytosis.*—As I have not had much experience with this method I should like to give the conclusions arrived at by Dr. L. B. Wilson of Rochester, Minnesota.

1. Sondern's hypothesis, that the polynuclear percentage is an index of infection, the total leucocytosis an index of body reaction, and their proportional relationship an index of resistance, seems to be supported. The more important exceptions to this are in moribund cases, and perhaps in children.

2. As practically applied in early appendicitis cases the disproportional polynuclear increase indicates a more or less severe infection, which is not being properly cared for by the body. The higher and longer this line, the more serious the case.

3. A proportional polynuclear percentage or a disproportionate polynuclear decrease, if well marked, indicates mild or well-cared-for infection.
4. The value to the surgeon in early cases is but little, since most early cases are operated on. It may be of some value negatively in indicating that the supposedly acute exacerbations of chronic appendicitis are not present.
5. In cases between the fourth and fourteenth days, the resistance-line is of great value to the surgeon in indicating the patient's poor resistance and the necessity for immediate operation. The operative findings in these cases bear out the leucocyte determination with wonderful accuracy.
6. A horizontal or falling resistance-line indicates that the patient is taking care of the infection. If the infection is severe, as shown by a high though falling line, the patient may perhaps best be given medical treatment rather than submitted to operation.
7. In any severe case the resistance-line should be determined daily; and should the line begin to rise, the patient may be submitted to operation.

13. *Abscess.*—When the tumour does not end in resolution an abscess is generally formed. The occurrence of abscess may be indicated by the temperature persisting at its original high level, or more often by the increase in rapidity of the pulse while the temperature becomes lower. Fluctuation is rarely detected at first, but the presence of a hard tumour with extreme tenderness and high fever generally denotes the presence of pus. So it is bad surgery to wait for the fluctuation before interfering. Not infrequently the tension within the abscess may burst suddenly through the surrounding adhesions into the peritoneal cavity and set up diffuse peritonitis. Again, it may burst through the bladder wall and be evacuated with the urine, as in one of my cases, or may burst through the external abdominal wall or into the intestinal canal. When the abscess burrows outwards, the overlying skin becomes œdematous, tender, red, and raised. In two of my cases I found the abscess burrowing through a small hole in the wall beneath the skin and there forming a large subcutaneous abscess. In these cases I was not quite sure whether the abscess was connected with the peritoneal cavity or simply an extraperitoneal abscess until I opened and examined the inside. Again, the abscess is sometimes found in the pelvis. This case could not be distinguished from simple pelvic cellulitis until the operation.

In one case of mine the abscess appeared behind instead of in front, so that a fluctuating tumour was found in the lumbar region.

Undoubtedly in some cases, even when an abscess is formed, the patient gets well without the pus being evacuated. I have seen one case in which the presence of pus was confirmed by puncture and by a fair-sized fluctuating tumour, but it disappeared the next day. I think this case was evacuated through the intestinal canal. Unfortunately, the motion after puncture, although said to have been suspicious, was thrown away and the point could not be ascertained. But there cannot be any doubt that the presence of a small quantity of pus is not against resolution taking place.

Finally, I should like to mention the symptoms and signs of the sudden rupture of an abscess into the peritoneal cavity as I saw one at the time: (1) Sudden excruciating pain in the abdomen running across from the appendicular region to the epigastrium; (2) difficulty in breathing; (3) subnormal temperature; (4) rapid pulse; (5) the disappearance of the tumour in the right iliac fossa; (6) rigidity of the abdominal wall; (7) the abdomen contracted and not distended; and (8) cold sweat.

14. *Diffuse peritonitis.*—This is generally due to perforation or gangrene of the appendix and only occasionally to rupture of a localised abscess. The following conditions may be noted: (1) Usually sudden; (2) rigidity of abdominal wall; (3) pain and tenderness all over; (4) gradual disappearance of abdominal respiration; (5) no passage of gas or fæces; (6) nausea and vomiting; (7) temperature subnormal at first; (8) pulse rapid from the first; (9) the abdomen at first contracted and then rapidly distended; (10) lies in the typical position on his back with legs flexed; (11) facies Hippocratica (abdominalis); and (12) in most severe cases the patients die quickly with toxæmic symptoms. Diffuse peritonitis is the most serious complication of appendicitis, and the only remedy for it is to prevent its occurrence by an early operation in severe cases, and when it occurs by immediate operation except in cases with extreme shock. The course of these cases in which diffuse peritonitis has occurred is more rapid than other cases, as is shown in the danger table.

15. *Intestinal obstruction.*—The obstruction is sometimes caused by paralysis of the intestine or by inflammatory adhesions. I should like to give a brief history of one case. It was that of a young lady, aged 24 years, with a history of constipation of about a week's duration, gradual distension of the abdomen, abdominal pain, and tenderness with slight fever. On examination the abdomen was found to be enlarged generally, and there was a large tumour of the size of a fist just to the right of the umbilicus. It was tender, and although dull on percussion there was suspicion of fluctuation. The temperature was not above normal, but the pulse was rapid and above 100. Nothing was obtained by an enema. Nausea was present. The diagnosis was uncertain except that the case was one of intestinal obstruction. So laparotomy was performed. On opening the abdomen the

tumour was found to be an abscess situated on the right side of the spine. No appendix was seen in the peritoneal cavity. The small intestine was paralysed and gangrenous patches were detected. As it was risky to incise from the front through the peritoneal cavity, another incision was made from the right side. Through the latter incision the abscess was reached and fæcal-smelling pus was evacuated. It was a post-peritoneal appendix abscess, placed wholly outside the peritoneum. This patient died three days afterwards without the obstruction being relieved. I think this case is one of those rare cases of obstruction due to the pressure on the superior mesenteric vessels, their constriction leading to the gangrene of the intestine. I have met two other cases of obstruction due to a similar cause.

Danger Symptoms and Signs.

1. Continual high fever at the commencement. 2. Frequent rigors at the commencement. 3. Early and frequent vomiting. 4. Sudden lowering of a high temperature without other sign of improvement. 5. Sudden disappearance of severe pain. 6. Abscess. 7. The discrepancy between the pulse and temperature. I mean by this that the proportion between pulse and temperature is abnormal. I consider this as one of the most important indications for operation and a sure sign of the approach of danger. On the preceding page I give a table of 50 consecutive cases of acute appendicitis to show the comparison of pulse and temperature. 8. Diffuse peritonitis.

These pulse and temperature rates were taken at the time of admission, and chiefly by this sign I have decided to operate at once or wait till the inflammation is localised.

It will be noticed in this table that the frequency of pulse in comparison to the temperature in the cases of diffuse peritonitis is striking. The more severe the case the more evident is the disproportion. Of course, this is not quite definite as there are exceptions, and before operation other facts must be also considered. Still, I think this is very important and must always be kept in mind.

Complications after Operation.

1. *Abdominal hernia.*—I had 4 cases of this condition. Two cases were operated on by the method of overlapping flaps and were quite cured; the other two were slight, and so far no operation has been done

2. *Fæcal fistula.*—Four cases. One case was completely cured by an operation. The perforation was near the surface and was sutured without much trouble. Another case was operated on three times without much success, but was cured completely in time by simple daily dressing and application of caustic. The two other cases would not heal for a long time, although several operations were done. The patients, getting impatient, asked for radical operation in another hospital, and they both died from diffuse peritonitis within a short time after operation.

I think that fæcal fistula, unless easily sutured, ought to be left to a more simple method than the radical operation, which separates the surrounding adhesions and often sets up diffuse peritonitis. I have seen many obstinate cases of fæcal fistula heal in time by simple methods. It certainly requires patience in patients and doctors, but it is undoubtedly safer.

3. *Parotitis.*—I have met with one case of one-sided parotitis occurring a few days after operation. It was incised and soon got quite well.

4. *Liver abscess.*—I have seen one case. As this case has been already fully described I will give only a brief account. The patient had multiple pyæmic abscesses in the liver, and although six abscess were opened yet he still had rigors with occasional high temperature and general weakness, the result of toxæmia.

5. *Cholecystitis.*—I have seen only one case. Shortly after operation the patient complained of pain in the right costal region with tenderness over the gall-bladder. He developed a slight jaundice with symptoms of indigestion. It was temporary and he quickly got over the trouble.

6. *Toxæmia.*—I have seen a few cases which showed symptoms of toxæmia and in which the patients died in spite of various forms of treatment. Generally in these cases I could find no bad signs in the operative field, and could account for no other reason than the absorption of toxin before the operation and its continual activity. In one case I was allowed to open the abdomen again to see the condition of the peritoneal cavity. There the peritonitis was subsiding and I could find no cause. Undoubtedly there are some cases which prove fatal from this cause. It is really very disappointing when, in spite of the improvement in the abdominal condition, the patient succumbs. The only safeguard against this complication is the evacuation of pus as soon as diagnosed.

7. *Intestinal obstruction.*—Several cases had partial obstruction after operation, especially cases where the adhesions had been extensive. In some cases of diffuse peritonitis, owing to paralysis of the intestine, the obstruction was more pronounced, but mostly these cases were temporary and amenable to treatment.

8. *Acute dilatation of the stomach.*—I had three cases. One case was slight and presented a moderate epigastric dilatation with nausea. By the passing of a bougie once and by withdrawing a small quantity of green fluid the patient was at once relieved and there was no recurrence. So whether the case was one of this condition or not is uncertain. The other two cases presented much dilatation of the stomach with frequent vomiting of a large quantity of green fluid at intervals. Passing a bougie and washing the stomach were done; one patient recovered and the other died. The last case was confirmed by post-mortem examination directly after death. It was wonderful how the patients were immediately relieved by the withdrawal of fluid and washing out the stomach. In later cases where there was any suspicion of stomach dilatation I at once passed a bougie and if necessary washed out the stomach. I think this preventive method would be the best guard against the occurrence of this serious complication.

9. *Ligature abscess.*—I have met with three cases in which a small abscess was found at the site of the wound and a ligature was discharged. Every time it was due to silk and in consequence I use catgut now.

10. *Diarrhœa.*—I have met with two cases, in both of which there was obstinate diarrhœa after operation.

11. *Secondary abscess.*—In one case, although I evacuated an abscess at the time of operation and could find no other, yet the temperature rose again and another abscess was found. The patient had a large abscess extending from the right pelvis to the level of the umbilicus on the right side and it was evacuated. A few days later the temperature rose again and I found another large abscess in the left iliac fossa.

The Condition of the Field of Operation.

In simple acute appendicitis I found the appendix generally swollen, red, congested, and adherent to surrounding tissues—especially to the cæcum and great omentum. In some cases a small quantity of pus existed in the appendix. In two cases I found the tip of the appendix cut off as if by the previous attack, so that it was very much shortened. In gangrenous appendix, the gangrene is usually partial, but may be quite complete. Perforation may take place anywhere, but it seemed to occur more often nearer the root than the tip. The perforation was usually one, but in a few cases it was multiple. I saw two cases in which I never expected recovery, and simply left the wounds with gauze packing, but these cases both recovered completely, although one for a time showed symptoms of partial obstruction. I think that in these cases it is better to leave the repair to nature and not to interfere, as by the removal of the gangrenous portion. In some cases I never found the appendix, although I systematically searched for it. Some surgeons have said that the appendix never disappears, but I could not quite agree with them because I have seen the appendix almost like a thin thread of tissue, and also could not find it in its proper situation by the cæcum or anywhere else. I have at the same time found a perforation at the site of the normal appendix. Again, in the two cases of shortened appendix which I quoted before there had been previous attacks, and I did not find the tip anywhere. So I should think that the appendix may be completely disorganised and may disappear in severe attacks. In one case where a perforation was present without the presence of appendix in the pus or anywhere, a worm was protruding through the hole. (This case was not operated on by me, but by my former assistant, Dr. Hanaoka). At first sight it was mistaken for the appendix. The adhesions in some cases are dense and make the operation most difficult. In diffuse peritonitis the pus may be anywhere, but most frequently it is in large quantities in the lower abdomen. A small abscess is usually situated round

the appendix. The pus may be thick or thin, yellow, watery, dark, &c.

Diagnosis.

The diagnosis is not usually difficult. I will now describe the experiences I have had.

1. *Localised peritonitis due to perforation of the cæcum.*—The case was diagnosed as acute appendicitis owing to its having (*a*) sudden acute pain in the appendix region occurring after eating a large quantity of green vegetables at dinner; (*b*) high fever; and (*c*) localised tender tumour. At the operation it was found to be perityphlitis due to the perforation of the cæcum close to the appendix by a stalk of the green vegetable. The appendix was normal.

2. *Tuberculous peritonitis.*—In this case the symptoms were acute with sudden pain in the right iliac fossa and with high fever and rapid dilatation of the abdomen. Tenderness was present in the appendicular region, but at the operation it was found to be tuberculous peritonitis with acute symptoms and with swelling in the region of the appendix.

3. *Pneumonia.*—The subject of this case was a man 30 years of age suffering from high fever, slight pain, and tenderness on the right side of the abdomen and a rigid lower abdominal wall. At first sight it looked like an attack of acute appendicitis, but the rigidity was not constant and only occurred at intervals. While waiting the patient brought up a large quantity of blood and passed over the pneumonic crisis.

4. *Ruptured gall-bladder.*—This patient was not operated upon by me, but I saw the case. There were high fever, a large tender tumour in the appendix region, and a previous history of pain on the right side of the abdomen. On opening the abscess a large quantity of purulent bile came out. A short time after operation two gall-stones were discharged through the sinus. Later the patient died and rupture of the gall-bladder was confirmed by the post-mortem examination.

5. *Typhoid fever.*—A few cases of typhoid fever were sometimes suspected of being acute appendicitis at first. When the conditions are combined diagnosis is difficult.

The Results of Treatment (Operations in Acute Cases).

Adhesions	19
Localised abscess	28
Diffuse peritonitis	25
Total	72

By adhesions I mean those early cases where only inflammatory adhesions are present and no pus. Of the 72 cases, 55 were cured and 17 proved fatal. Of the 19 cases of adhesions 18 were cured and one patient died. In the last-mentioned case the patient died five days after operation with high temperature and cerebral disturbance which commenced two days previously. No cause was found in the abdomen, and the wound was getting on well. Whether this was due to cerebral embolism or toxæmia I could not say. Of the 28 cases of localised abscess, 26 were cured and 2 patients died. Of these two fatal cases one patient had suffered from tuberculosis of the apices of both lungs, and his death was no doubt accelerated by it, while the other patient represented a very severe case of a large abscess having the appendix gangrenous and separated from the cæcum, so that it was floating in the pus, and there was a hole in the cæcum. This patient died from toxæmia two days after the operation. Of the 25 cases of diffuse peritonitis 11 were cured and 14 proved fatal. This shows a mortality of 56 per cent., but this has been lessened among the later cases. The first six cases were all treated by washing out the peritoneal cavity with warm saline solution. Of these only one case was saved, showing a mortality of 83·3 per cent. The other 19 cases were treated by simple wiping of the peritoneal cavity, with Fowler's position and Murphy's saline post-operative treatment. Of these, 11 were cured, showing the reduced mortality of 42·1 per cent. There is no doubt whatever that the wiping method, combined with the Fowler's position and Murphy saline treatment, has brought about a radical change for good in peritonitis.

As regards the appendix, 44 were removed and 28 were not excised.

The above figures show the good results obtained in both simple or non-suppurative and localised cases, but although improved by the recent advance in the peritonitis treatment, the mortality is still high in the diffuse cases, showing 42·1 per cent.

Treatment.

Much has been written and said about the treatment of acute appendicitis, but even now no definite conclusion has been arrived at. However, the present opinion among surgeons is that the best treatment for acute appendicitis is the immediate operation at its commencement, and I will now summarise the advantages of early operation.

1. It is the safest method, because we never know how soon the appendix may become gangrenous or may perforate, causing serious, if not fatal, complications. The rapidity of the onset of complications can never be foreseen. There have been many examples of gangrene or perforation occurring within the first few hours of the appearance of any sign of the disease. In one of my own cases a gangrenous appendix was found 19 hours after the commencement of pain.

2. The operation is easily done owing to the absence of serious adhesions. I have found often a great difficulty in later stages to find the appendix, and in some cases have never found it owing to dense adhesions. Besides, the absence of pus is a great advantage and the part can be manipulated without fear. Of course, in a few cases, even in the early stage, there is a small quantity of pus, but this is not usual.

3. The patient is completely cured once for all. As the appendix is removed he is cured for life and he need not fear recurrence. In later stages, when some complications had occurred, it has been often found difficult to excise the appendix. If the appendix is left behind you can never be sure of a complete cure.

4. The convalescence is short—usually about a fortnight. Besides, as the wound is clean and can be closed up, there will be no fear of abdominal hernia or other post-operative complications. When suppuration occurs the convalescence is generally greatly delayed.

5. As regards the later stage, let me quote from Dr. Murphy:—

> Should we operate in the intermediate stage, during the increasing or spreading inflammatory process which may mean anywhere from the second to the fifth day? In this stage we may have the circumscribed abscess around the appendix, an active inflammatory process of the neighbouring tissues or organs, or the early pathologic changes of a circumscribed or general peritonitis. We often find the temperature and pulse high, meteorisms, intestinal paralysis, and acutely infected tissues, with manifestations of severe intoxication at this stage. Shall we then operate?

This is the point which is now the centre of discussion among surgeons.

Let me now give an extract from a paper by Dr. Clarence A. McWilliams of New York, published in "Annals of Surgery," June, 1910:—

> The answer to this question divides the surgical world into two camps: the one advocates the Ochsner treatment of diminishing peristalsis and delaying operation in the hope that the diffuse or general peritonitis will subside into a local process and form a circumscribed abscess which can be opened later when the severe abdominal symptoms and general toxæmia have subsided. Some of their statistics are alluring; but, before being convincing, it will be necessary to know how many patients treated in this way die without localising the process into an abscess, hence go unoperated. I have seen no such statistics. Patients who have strength enough to survive the battle are operated upon and the unfit are eliminated. This method seems ideal for the statistics of the operator, and perhaps better calculated to minister to the surgeon's reputation than to the safety of the patient. How is anyone to tell in advance whether a given spreading or diffuse peritonitis will not go on to a general and fatal peritonitis?
>
> The Ochsner method of treatment has been widely misunderstood and wrongly applied. Many have falsely interpreted it to mean that operation in all acute cases, even in the early stage, should be delayed, and great harm has been done because of the letting slip by of the most favourable time for successful operation—namely, at the onset. Perhaps it would be well to outline the Ochsner method of treatment in order that there may be no misunderstanding as to exactly what is meant. We may divide it in two parts. The first finds few dissenters among surgeons, and relates to efforts which should be used to diminish peristalsis, hoping thereby to limit the spread of the inflammation. It consists in the use of gastric lavage, the giving absolutely of no nourishment of any kind and no cathartics by mouth, the giving of no large enemata, the continuous administration of normal salt solution by rectum by the drop method, and the giving of nourishment exclusively by the rectum.
>
> The second and more criticised portion of the Ochsner treatment consists in delaying operation in the severe cases in the hope that, by the employment of the means outlined above, peristalsis will be so diminished as to limit the spread of the diffuse or general peritoneal inflammation, and that a local abscess will form which can later be opened.

The classification adopted by Sprengel is certainly the most convenient, but is, I think, too arbitrary. He classifies the operations in three stages as follows: (1) early

operations, those under 48 hours; (2) immediate operations, from the third to the sixth day; and (3) late operations, from the sixth day onwards. Because the cases do not all take a similar course, and the more severe the more rapid is the advance of the inflammation, I should like to divide them into uncomplicated and complicated.

Unquestionably the best time for operation is at the commencement of the illness, but unfortunately we usually do not get our patients at so early a stage, and most often see them when the condition is more advanced. The cases usually coming into the hospital are severe cases. The large percentage in cure of all uncomplicated acute appendicitis is the chief factor in preventing them passing into the surgeon's hand so as to have the radical operation done. By this I do not mean that all the cases must be treated surgically, for most cases of slight nature, or, indeed, fairly severe cases of acute appendicitis, can be treated with complete safety without an operation and be cured. In other words, the uncomplicated cases ought to be operated upon in the early stage, but there is no "must."

As regards the complicated or severe cases, I should operate in all cases except where the patient's condition is very weak or where after a few hours of Ochsner's treatment the patient shows no improvement. Even very severe cases are sometimes cured by Ochsner's treatment, but if the results obtained of equal numbers of diffuse peritonitis treated by this method and by those of the Fowler, the Murphy, and wiping methods be compared, I have no doubt that the last named will show the best percentage. I think the long continuance of Ochsner's treatment in diffuse peritonitis is more dangerous than is laparotomy.

In certain cases I have tried a simple opening and letting out of pus combined with the other treatment. I think this is much better than without an operation. The opening can be done with local anæsthesia.

Some object to operation in the spreading inflammation stage that the inflammation is not arrested by it, but, on the contrary, that it gives stimulus to it and leaves the patient in a worse condition. I do not think so from my own experiences. I found even in cases where pus was present that both contamination and inflammation were prevented. Certainly the localised abscess is safer to operate upon than are the early soft adhesion cases, but with care the spreading of pus can be prevented.

In my cases I took the following steps:—

1. *Mild cases.*—(*a*) Fluid diet; (*b*) complete rest; (*c*) local application of ice-bags; (*d*) leeches sometimes; (*e*) bowels opened only by small enemata; (*f*) purgatives never used, except rarely in very early stage; (*g*) as regards morphia or opium, it is not my habit to give it except where the patient bears the pain badly, causing restlessness, sleeplessness, &c., because it often masks the symptoms and signs, and one may be deceived; (*h*) if the radical cure was required, the operation was done without hesitation.

2. *Fairly severe uncomplicated cases.*—I treated them in the same way, but at the slightest sign of any danger I operated.

3. *Severe or complicated cases.*—Except where the shock was extreme, my advice was to operate at once. In some cases I watched them for a short time under the delaying method, but I found the immediate operation attended with better results than the other. So in future I should not hesitate to operate at once.

Operation.

1. *Simple or uncomplicated cases.*—An incision was usually made longitudinally through the right semilunar line. This incision is the most convenient to reach the appendix, and when necessary you can easily widen it both upwards and downwards so as to give more space. It is also attended with very little hæmorrhage, which is another advantage. The occurrence of hernia is not frequent in Japan as the band (Obi) worn acts as a complete truss and prevents its occurrence. After opening the peritoneal cavity the appendix is sought, and after tying the mesentery the appendix is cut off near its root and the stump is turned in with catgut purse-string suture. The abdominal wound is closed in layers.

2. *Severe or complicated cases.*—The incision is either made through the semilunar line or over the prominent tumour. In the diffuse peritonitis the first incision was generally made in the mid-line followed by another incision in the right semilunar line after the diagnosis was confirmed. All the wounds were generally left open except the median one. The partial closing of the wound in suppurating cases may be useful in preventing the occurrence of hernia, but I think the large wound safer, as the site of suppuration can always be in view, and any change in that part can be seen. The wound in bad cases is packed with iodoform gauze, and for others a drainage-tube or cigarette tube is used.

As regards the appendix, I generally look for it and remove it, because if it is left the operator can never be sure of certain cure, and, moreover, he may be troubled with an obstinate sinus. But where the appendix cannot be found owing to dense adhesions I leave it alone. Again, if in severe cases the patient's condition is bad, I do not look for it, but am satisfied with simply letting out pus. If not found immediately it should not be searched for, as it is usually placed in the retrocæal position and very difficult to get at. As I said before, the appendix in some cases is disorganised by the inflammatory process and may disappear altogether.

The stump of the appendix is usually turned into the cæcum, but in some cases where the cæcum is soft, in consequence of the extension of the inflammatory process, or the patient is in bad condition, I am satisfied with simply ligaturing and cutting off.

Since the first year I have never resorted to the washing out of the peritoneal cavity by the saline lotion. I have now not the slightest doubt that the improvement in the results of the severe cases is due to the wiping away of the peritoneal pus, Fowler's position, and Murphy's saline treatment.

HENOCH'S PURPURA WITH ENTERIC INTUSSUSCEPTION.

REDUCTION; INTUSSUSCEPTED AREA GANGRENOUS; RESECTION OF 2 FEET 5 INCHES OF GUT; IMMEDIATE END-TO-END UNION; RECOVERY.

BY H. BETHAM ROBINSON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO, AND LECTURER ON SURGERY AT, ST. THOMAS'S HOSPITAL; CONSULTING SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN.

INTESTINAL symptoms with hæmorrhage from the bowel have been well recognised as a frequent associate in cases of Henoch's purpura. With a limited swelling, especially in the neighbourhood of the ileo-cæcal valve, there is considerable difficulty, if it be possible, in deciding without operation whether the swelling is due to hæmorrhagic infiltration of the bowel wall or to an intussusception. In the following case this difficulty did not present itself, for the size and shape of the swelling and its mobility pointed to an intussusception located in the small gut.

A boy, aged 5 years, was first seen by Dr. Braidwood on Dec. 24th, 1909, on account of illness of two days' duration. The temperature was 102·6° F. The left elbow-joint was swollen, hot, and painful; the left foot was swollen on the dorsum and hot, and other joints were painful but not swollen. There was an evident purpuric rash on the thighs and lower part of the trunk, with distinct swelling and discolouration of the left side of the scrotum. The child was put upon salicylate of sodium and in two days the temperature came down and the joints appeared about normal. On the 27th the child was not so well and complained of abdominal pain; three stools were passed, and the last one consisted of a considerable quantity of fluid and mucus flecked with blood. The next day, being in much the same condition, except that there was more evidence of blood in the stools, he was brought up to St. Thomas's Hospital and admitted under my colleague, Dr. H. G. Turney, but later in the day was transferred to me for operation.

On admission he was still rather tender about the affected joints. About the ankles were a few dusky spots, and around some recent scars on the right elbow there was a definite purple discolouration. The abdomen was not particularly distended, but a very well-defined lump could be felt below the umbilicus, extending from the edge of the right rectus over the mid-line almost to the outer edge of the left. Over this area there were some muscular rigidity and tenderness. The temperature was 99·6° F., the pulse was 124, and the respirations were 28. The finger on rectal examination came out covered with dark blood without mucus. There was no history of vomiting.

Operation was decided on, and examination of the abdomen

when under the anæsthetic showed the abolition of the previous rigidity; a lump of the size of the palm of the hand was felt, consisting of two rather elongated elastic tumours, almost parallel, with a sulcus between them; this lump could be easily moved about the abdomen and be pushed up under the liver. Per rectum, on pushing the lump downwards it could be felt in Douglas's pouch. The rectus incision was used, the muscle being pulled inwards and the fascia and peritoneum below divided together. A large quantity of blood-stained serous fluid escaped, but in it were no lymph flakes. A large enteric intussusception was brought out of the wound looking "like a twisted horse-shoe." The intussuscipiens was very distended and dotted all over with little hæmorrhagic spots; the entering bowel and the mesentery were very tightly nipped at the entrance, but the proximal bowel was of quite healthy colour and only thickened from contraction; there was no lymph on the surface of the intussusception. The neighbouring glands in the mesentery were enlarged. The intussusception was slowly reduced by pressure from below with a little traction at the last; there were no adhesions. During reduction a considerable quantity of blood-stained serum was set free from between the layers. The entering bowel was very contracted and at the beginning not particularly dark, but it soon became so. The returning layer was prune-coloured except over the mesenteric border, where it was much thinner and of a greyish colour; the walls of this part and of the intussuscipiens were generally very thinned and distended, showing no contractility. The mesenteric vessels to the distal part of the intussuscipiens pulsated well, but those to its proximal part only feebly; there was no pulsation in the vessels to the returning layer and to the distal part of the entering; the pulsation was very poor in the vessels supplying the first part of the entering layer. There was no hæmorrhage into the mesentery, but its vessels felt blocked. It was obvious that all this gut was beyond recovery and must be resected, and to get healthy bowel at each end 2 feet and 5 inches had to be removed; the thrombosed area of mesentery was also cut away. The child's condition permitting it and the upper part of the intestine not being very distended, it was decided to do an immediate end-to-end union. In suturing the ends were carefully approximated first of all at the mesenteric border; the edges through all the layers were united with fine catgut, and then through the sero-muscular coat a continuous Lembert's silk stitch was used, care being taken by knotting not to constrict the bowel. The edges of the mesentery were united with fine silk. The omentum was folded over the line of union, not stitched. No other hæmorrhages were discovered in the bowel. The abdominal wall was done up in layers. The union was 15 inches from the ileo-cæcal valve. There were no thickenings like enlarged Peyer's patches in the excised part or beyond. In the evening after the operation the pulse was 176, the temperature was normal, and the respirations were 22.

On the next morning the temperature was normal and the patient's condition generally was satisfactory. In the afternoon the temperature rose to 103°, while the pulse was 180, and the patient was very restless, but in the evening the temperature dropped to 101·4°. On the 30th and 31st there was a gradual fall of temperature to normal, where it afterwards remained, with reduction of the pulse-rate to about 100; this was attended with similar improvement in his condition. The stitches were removed from the wound on Jan. 5th, 1910, when some superficial suppuration was found at the lower part, but there was no sloughing. The patient got up on the 15th. There was some sluggishness at first about the action of the bowels, but this soon passed off. The treatment did not in other ways differ from that ordinarily used in intestinal surgery.

On Jan. 19th there was a sudden rise of temperature to 104·4°, which was rather alarming; this was associated with a severe sore-throat, with ulceration and enlarged glands in the neck, and later followed by tracheitis and bronchitis. The temperature was high from the 19th to the 28th and then it fell by lysis. All this time the patient was perfectly free from any abdominal symptoms and the bowels acted normally. He left the hospital cured on Feb. 2nd, five weeks from the operation, which time might certainly have been shorter by ten days but for his sore-throat, &c., probably due to influenza.

The first point for consideration is, Was this a true case of Henoch's purpura? Many cases have been so considered on rather scanty evidence, but here the state of the joints, the intestinal hæmorrhage, and the rash seemed definite enough. If there were any doubt, the association of the enteric intussusception gave additional support to the diagnosis. Although comparatively a rare complication, it was, occurring at the age of five years, a little beyond the ordinary period when intussusception is met with.

Sutherland has stated that the hæmorrhage into the bowel wall causes paralysis of that segment, and hence intussusception. In my case there was no doubt that hæmorrhage had occurred into the bowel wall antecedent to the other changes, and the beginning of the marked blood staining was in the region of the apex of the intussusception.

Whether there was bile in the rectal blood or not, a clinical sign pointed out by Barnard to distinguish between the swelling of the bowel wall in Henoch's purpura and the block caused by an intussusception, was not here tried, for the size of the tumour and its shape were both against a simple hæmorrhage having occurred into the bowel wall. The double tumour, with the sulcus between, was before operation rather puzzling, but inspection showed that this had been produced by the pull of the mesentery, which did not strike one at the time.

As to the treatment, the child's condition and the absence of over-distension of the proximal bowel warranted an immediate end-to-end union, which produced such a happy result. It is possible to urge that if sloughing had occurred at the line of union (sloughing of wounds being known to be frequent in these cases) the result might have been disastrous; as this sequel is not certain, it is worth while risking a little to avoid the inconvenience of an artificial anus with a secondary operation to follow.

Upper Wimpole-street, W.

THE RELIEF OF SYMPTOMS OF PROSTATIC OBSTRUCTION BY ELECTRICAL TREATMENT.

BY JOSEPH S. BOLTON, M.D. EDIN.

THIS modest title is purposely chosen. A more ambitious stand might have been taken and some mention made of reduction in the size of the prostate, but it is better to postulate too little than too much. All that is implied in the title can be demonstrated; improvement in symptoms is easy to ascertain and register. Every patient can appreciate the difference between a disturbed night and a good one. But when the size of the prostate is in question and exact measurements are required difficulties begin. Also, when it is sought to compare the size before and after treatment, not only is accurate observation necessary, but a very exact and retentive memory, especially if several weeks have elapsed between the observations. The desire to record diminution is apt to mislead the judgment. Even when the operator is certain that there is considerable shrinking it may not be easy to demonstrate. But if the symptoms are cured and the patient made comfortable the chief end of treatment has been obtained.

The claim now put forward may be thus stated. That by a treatment which is harmless and painless, so that it can be administered to the aged and feeble, so much improvement can be brought about as to make the patient comfortable, remove the necessity for catheter interference, and restore his hope and confidence for the future.

The method of treatment is to pass an electrode into the rectum and administer high-frequency currents. The electrode is so placed that it lies against the posterior surface of the prostate. The current is taken from the top of the resonator. The local effect can be increased by the operator placing his hand flat upon the abdomen just above the pubes. In urgent cases the patient should be treated every day for a quarter of an hour, but in more chronic cases three times a week will be sufficient. In my earlier cases I used a solid metal electrode, and I continue to use this in all cases where congestion is a marked feature and where irritable nerves require soothing. But for large hard prostates a more stimulating treatment is indicated. For this purpose a vacuum electrode may be used, or, better still, a condenser

electrode so modified that all the electric bombardment is in the region of the prostate.

In a former paper upon this subject which was published in THE LANCET of April 13th, 1907, I gave particulars of my early cases. These patients, so far as I have been able to trace them, are still doing well. Also the results recorded at that time are borne out by further experience.

My most successful cases have been those where congestion and irritation rather than size of prostate have been the prominent features. A medical man, aged 59 years, had been waking almost every hour of the night and rising several times to pass urine. This condition had been gradually getting worse for several years and he had tried medicinal treatment without avail. But though the symptoms were so disturbing the enlargement of the prostate was not great. He was treated three times a week for five or six weeks, using the solid metal electrode, and could then sleep the whole night through without disturbance. The cure was perfect and lasting.

A very similar case was that of a man, aged 60 years, who had to be relieved with a catheter three years ago and had been troubled with disturbed nights ever since, rising five or six times to pass urine. After seven treatments he was able to go through the night with only one disturbance. A marked feature in this case, as in so many others, was that he had to wait for his urine to come. After a few seconds it would begin to dribble, and a little later it would come in a fair stream. This condition is amenable to high-frequency current treatment.

Another patient of about the same age was troubled with the opposite condition. After a cup of tea or dram of whisky the desire to pass urine would be so urgent that if he could not obtain immediate relief he would sometimes find himself wet to the boots. There was no marked enlargement of the prostate, and the trouble was not due to retention. His urine was clear, faintly acid, of specific gravity 1022, and contained neither albumin nor sugar. The condition was greatly improved by the treatment. The patient was, however, advised to abstain from whisky in future, and to be very moderate in the use of tea and coffee.

Many patients have been made worse by the well-intentioned advice of surgeons whom they have consulted. An elderly man with symptoms of enlarged prostate is warned of his danger and advised to keep a catheter and antiseptics for any emergency. He is also told never to delay when he has a desire to micturate, but carefully to avoid holding his urine too long. The fear of a stoppage is always before his mind, and he urinates doubly as often as he need. In time the act becomes a habit and his bladder expects to be emptied frequently by night as well as by day. This faulty habit cannot be overcome without assistance. High-frequency treatment will remedy the cause and restore the confidence. Such a case was treated for me by Mr. A. Primrose Wells.

The patient was 73 years of age. He was troubled with frequency of micturition, especially in the day-time. There was also delay in starting the stream, and sometimes dribbling after passing it. He consulted a surgeon, who drew off more than a pint of urine, and advised him to have his large prostate removed. A physician reported unfavourably on the condition of his heart, and fearing operation he decided upon electrical treatment. The result was eminently satisfactory. There was improvement in all the symptoms and in the health of the patient. The prostate also was reduced in size.

In another case treated by me last summer the patient was 70 years of age, and symptoms of enlarged prostate had been gradually getting worse for eight or ten years, but he had never had stoppage. The prostate was of moderate size, but he had much pain and discomfort in the region of the bladder and urethra, and rose eight or ten times a night to pass urine. After three or four weeks' treatment the pain left him, but the nights were just as disturbed. It was only after two months' treatment that he obtained good nights. I saw him ten months after the treatment, and the improvement was still maintained. He said: "I am as well as ever I was."

It is not possible to cure every patient, but relief is experienced by such a large proportion as to make the treatment worthy of trial in all uncomplicated cases. The results of the treatment may be summed up in a few words. Congestion in the blood-vessels and stasis in the tissues are relieved. The nerves are soothed. The intense irritability of the bladder which is such a marked feature of the disease passes away. The tone of the bladder muscles is improved, and as a consequence the size of the stream is increased and also the force of propulsion. The bladder becomes able to empty itself, and the urine returns to normal. The restoration of the confidence of the patient is no small help in lessening the frequency of micturition.

Is the prostate reduced in size? In seeking an answer to this question we must remember that the enlargement is not all due to overgrowth. Much of it is due to congestion. So there may be very considerable reduction in size without contending that high-frequency currents will remove fibrous overgrowth. It is important also to bear in mind that the prostate is often enlarged for years before it causes any trouble. The symptoms only show themselves when the vital powers begin to flag owing to advancing age. It is only natural, therefore, that high-frequency currents, by renewing to some extent the healthy vigour, will remove the symptoms of obstruction. But besides all this, probably no one who has watched carefully the course of treatment of a successful case will fail to be convinced that there has been considerable reduction in the actual size of the prostate.

Nottingham.

A REMINDER OF THE BATTLE OF OMDURMAN.

AN ACCOUNT OF THE REMOVAL OF HALF A SHRAPNEL BULLET WHICH HAD REMAINED EMBEDDED IN THE LEG OF AN ARAB FOR 11 YEARS AFTER THE BATTLE, SEPT. 2ND, 1898, TO DEC. 1ST, 1909.

BY J. B. CHRISTOPHERSON, F.R.C.S. ENG., M.A., M.D. CANTAB., M.R.C.P. LOND.,
DIRECTOR OF HOSPITALS, KHARTOUM AND OMDURMAN; SURGEON, KHARTOUM HOSPITAL, ETC.

Mr. H. Curtis's interesting account in THE LANCET of April 9th, 1910, of the extraction of a Mauser bullet with sequestra ten years after the Jameson Raid, impels me to send an account of a case I saw at Omdurman Hospital on Dec. 1st, 1909.

The Battle of Omdurman took place on Sept. 2nd, 1898. On Dec. 1st, 1909, 11 years afterwards, I removed half a shrapnel bullet and a piece of bone from an abscess cavity in a quondam Dervish's thigh. The abscess was deeply situated in the supero-antero-external aspect of the thigh (see Fig.) close to the bone, its walls being of a very tough fibrous tissue structure (1½ inches thick). It had given him no trouble until the last four months, during which time the swelling had increased rapidly. From this history I assume the bullet had lain quiescent and unnoticed for 11 years and had then become infected with the micro-organisms of suppuration, and the abscess which had formed in consequence had grown larger and larger until it was of the size of a moderate-sized lemon, and as the cavity ulcerated and necrosed the fibrous tissue wall had become increasingly thicker until there was a very appreciably large swelling, deeply connected, whilst the fibrous tissue wall of the abscess involved at last the skin itself.

An Egyptian doctor, whom the patient had consulted previous to coming to hospital, had already incised it and had extracted one small piece of bone, leaving a swelling with a discharging sinus. The bone was thickened for some distance up and down the shaft in the neighbourhood of the bullet, but the cavity was separated from the bone by some thickness of tissue. The scar of the wound of entrance (see Fig., A) was about 1 inch long and ½ inch wide, and the femoral artery could be felt pulsating beneath it. It was about 1 inch below Poupart's ligament. The firing party had been a considerable distance off; in fact, the man was apparently wounded by the opening volley of the battle, the bullet had ricocheted, was flattened, and grooved on one face, and was only half a bullet. It had passed in horizontally and had penetrated half-way through the thigh and no further.

The condition of the bullet and bone was the same as on the day the bullet was fired, excepting that there was a small deposit of some white salt on a part of its edge. The two pieces of bone did not present the appearance of

sequestra, therefore I assume that they were broken off by the bullet when it entered. They were apparently little altered during their 11 years' sojourn with the bullet amongst the thigh tissues. The man was hit at the same time in two other places (see Fig., C, D). A piece of shrapnel struck him on the right shin, grazing the tibia in its upper third (D),[1] and he also received a ·303 bullet on the outer side of his left knee-joint (C), which lodged beneath the skin behind the outer tendon of the vastus externus behind the joint.[2]

The man had an interesting story to tell. He was an Arab of the Jaalin tribe, who occupy the banks of the Nile in the Berber and Khartoum provinces, but he was born and brought up at El Obeid in Kordofan, and when the Mahdi appeared was following the trade of his father—a merchant. He joined the Mahdi and accompanied him from El Obeid to

C, Cross represents scar of wound of entrance of the ·303 bullet received at the same time, the dot behind being the wound of exit made by the native doctor after the battle to extract the bullet. D, The scar of the other fragment of shrapnel over the right tibia.

Omdurman. He did not remain in Omdurman town, however, during the Mahdieh, but went to Rufaa, a large village on the Blue Nile, where he cultivated land, from which place he was summoned by his emir to take part in the battle. The Battle of Omdurman took place at dawn on Friday, Sept. 2nd, and on the previous Wednesday evening the Dervishes forming the Khalifa's army were marshalled together and slept in the large open-air mosque, adjacent to the Khalifa's house in Omdurman. They moved out to meet the Anglo-Egyptian army on Thursday morning, sleeping that night in the dried-up water-course called Khor Shambat, about half-way between the battlefield and Omdurman town. Early on Friday morning they attacked the village of Ageiga where the British army had landed from the river, and this man was in the front rank of the right[3] of the three divisions[4,5] under the Emir Osman Azrak as they attacked. He was in the front rank during the first attack at daybreak, and was walking with his spear in his hand, and was adjacent to the hill Gebel Surgham when he was lucky enough to be wounded in three places simultaneously (see Fig.) by probably the first British volley. He fell and was carried back on a donkey into Omdurman, where a native doctor (Bossir) extracted the ·303 bullet from his left leg. He was well again in about a month, and quietly left Omdurman[6] to resume his work as a cultivator at Rufaa, and has been a cultivator there ever since. The shrapnel bullet commenced troubling him only four months ago, and he came to Omdurman to consult a doctor.

This case is also interesting from a surgical point of view in several ways. Ten years ago it was not an uncommon event for a retired Dervish to come to the hospital to have a bullet extracted, but naturally these interesting bullet cases grow rarer as time goes on, and it is now four years since I extracted the last from a man coming from El Obeid, the bullet (a ·303) lying under the left scapula. The specimen is half a shrapnel bullet, flattened and grooved, and evidently ricocheted—one which had struck some body in its flight—and had thereby been altered in its direction, &c.

A shrapnel is a shell weighing 12 pounds and containing 177 bullets, each weighing ½ pound ("Military Surgery"). Theoretically a shrapnel should explode into 100 or 200 fragments at a distance of 50 or 100 yards in front of the enemy.[7] Wounds produced by such a projectile are said to be not so serious as those caused by direct small-arm projectiles. Shrapnel bullets often remain embedded in the tissues as they have not sufficient velocity to make a wound of exit. Their serious feature lies in the liability to several bullets or fragments taking effect.[8] All these points are exemplified in the case I describe, and it may have been the other half of the same bullet that wounded the man in the right shin which entered the thigh and remained embedded.

The case is also an instance of what Longmore (p. 340) calls (quoting Hunter) the "instinctive provision in parts to remove themselves so as to bring extraneous bodies to the skin for their exit."[9] Longmore (p. 341) mentions the case of a man wounded 16 years previously by a canister shot at Maharajahapore in 1843, who stated he had not been inconvenienced until a short time before its removal in 1859 from the right supraspinous fossa. Longmore ascribes the unchanged condition of such foreign bodies after being embedded for several years in the body as due to the exclusion of access of air (p. 343). I assume that the full explanation is that so long as the micro-organisms of suppuration are excluded the body remains inert and unchanged, but as soon as micro-organisms of suppuration are introduced (through the circulation) then the foreign bodies become changed. It would appear that healthy tissues do not absorb foreign bodies, but deal with them by encysting them; in the case of a sharp pointed body (a needle) it may move, but as a rule they do not move. The "instinctive provision" spoken of by Hunter is the process of infection which takes place sooner or later, and it is then that extraneous bodies move and are brought to the skin for their exit by means of this process.

With regard to the treatment of fragments of modern projectiles left in the body, it would seem that sooner or later they (wherever placed) will become infected and give trouble, so that it is better to remove them if they can be located rather than leave them. In the case described by Mr. Curtis I should think the inconvenience caused by the presence of the Mauser bullet was due to its vicinity to a large nerve and was mechanical.

These cases have a practical bearing on everyday surgery. With regard to the absorption of ligatures and sutures used in operations, it would appear from the unaltered condition of accidentally introduced aseptic foreign bodies which remain embedded so long and undergo so little change (both organic (bone) and inorganic (bullet)) that normal healthy

[1] Perhaps the other piece of the same shrapnel bullet.

tissues and fluids of the body are inert towards them, and one would doubt very much the propriety of the term absorbable ligatures—i.e., meaning thereby ligatures which will be absorbed by the healthy tissues. There are, of course, various degrees of resistance to the chemical action of abnormal fluids of the body, such as pus and unhealthy urine. Of course, the various digestive secretions of the intestines must be excepted from this generalisation, but even in digestion micro-organisms play a very large part in the destructive processes of the disintegration of foreign bodies.

Omdurman Civil Hospital, Sudan.

THE ETIOLOGY AND DIAGNOSIS OF GERMAN MEASLES (RUBEOLA).

BY CLIFFORD BEARDS, M.B. OXON., M.R.C.P. LOND.,
RESIDENT MEDICAL OFFICER, LONDON FEVER HOSPITAL;
AND
W. L. GOLDIE, F.R.C.S. ENG.,
ASSISTANT RESIDENT MEDICAL OFFICER, LONDON FEVER HOSPITAL.

THE great majority of isolation hospitals do not admit rubeola or morbilli, and little opportunity is therefore offered of seeing any great number of consecutive cases of these diseases and recording their daily progress. At the London Fever Hospital special wards are set apart for these diseases and 2262 cases have been admitted since 1899, the last 500 of which have come under our personal observation. Of these admissions, 1335 have been cases of rubeola and 927 of morbilli.

Etiology.—The theory of the hybrid origin of rubeola from scarlet fever and morbilli has been abandoned and the specific entity of this disease is now fully recognised, although up to the present the causal organism has not been identified. As regards the infectivity of rubeola, it is probable that it is less than that of either scarlet fever or morbilli, and that the main channel of infection is by personal contact and not by fomites. Divergent opinions have been expressed as to the period during which the disease is infectious. It would appear, however, that it is short-lived, and we are inclined to think that it is probably limited to the prodromal and eruptive stages. The difficulty of calculating the incubation period is evidenced by the varying estimates of different observers. Some assign as short a time as five days, while others consider that it may be as long as three weeks. In the limited number of cases in which we have been able to exclude all but one source of infection the period of incubation has been from 14 to 16 days.

Season.—This appears to exert some influence on the prevalence of the disease, for the records of this hospital show a gradual increase in the number of cases admitted from January to March. There is a marked increase during April, May, and the early part of June, after which an abrupt fall in the number of admissions is very noticeable.

Sex distribution.—As regards the sex distribution of the cases under consideration, the numbers are fairly equal. Of the 1335 cases of rubeola, 580 were in males and 755 in females, or, expressed as percentages, 43·5 and 56·5 respectively. These correspond very closely with the figures for morbilli for the same period, which were 45·3 per cent. males and 54·7 per cent. females.

Age incidence.—Of the age incidence in these diseases the figures are as follows:—

Age-periods.	Rubeola.	Morbilli.
0-10 years	1·4 per cent.	20·2 per cent.
10-20 ,, ...	24·4 ,,	26.1 ,,
20-30 ,, ...	63·6 ,,	46·0 ,,
30 years and over...	10·6 ,,	7·7 ,,

It will be seen from this table that over 98 per cent. of our cases of rubeola occurred in patients over 10 years of age, as compared with 80 per cent. of the cases of morbilli. Owing to the fact that the patients in the London Fever Hospital are drawn from a somewhat limited class it is unfair to draw definite conclusions as to the age incidence of the disease, but considering the fact that the admissions in morbilli and rubeola both come from the same section of the community, it would seem that the latter disease has its maximum incidence at a somewhat later age-period than the former. This fact appears, to a certain extent, to be borne out by Goodall's figures for Homerton Hospital, where in a total of 925 cases of which 638 were morbilli and 287 were rubeola, 20 per cent. of the latter were over 10 years of age, as compared with 1 per cent. of the former. Further, it may be noted that epidemics of rubeola are not uncommonly reported at boarding-schools, whereas up to the present they have not been a marked feature in the board schools, especially among the infant classes in which morbilli is so rife.

With regard to the extreme periods of life, the London Fever Hospital records for the last 20 years only show 8 cases under 5 years of age, of which the youngest was aged 2, and 9 cases over 50 years, the oldest being 61 years. Scholl has reported a case in a child occurring a few days after birth, while Seitz has seen the disease in a woman aged 73. In the case of rubeola we find that only about 50 per cent. are certified as such, the majority of the remainder being sent in as measles, while a few are diagnosed as scarlet fever, though the reverse (scarlet fever for rubeola) very rarely occurs.

The mild nature and absence of complications and sequelæ in rubeola have been fully recognised, but occasional severe epidemics have been reported. Thus Edwards gives a mortality rate of 4¼ per cent. in a series of 150 hospital cases; Hatfield one of 9 per cent. among a poor class. As regards complications, bronchitis, pneumonia, enteritis, rheumatism, conjunctivitis, have all been reported. Hatfield, Kingsley, Cheadle, and Duckworth have all recorded cases of albuminuria, while Edwards had a rate of 30 per cent. of one series of 166 cases, and 3 per cent. in another of 100 cases (quoted from Welch and Schamberg). These results are in striking contrast to those of the London Fever Hospital. 1939 cases of rubeola have been admitted since 1879, and amongst these there have been no deaths. In the last 478 consecutive cases the only complications observed have been "rheumatic pains" on two occasions, and transitory albuminuria in seven patients.

Premonitory symptoms of rubeola.—The period of invasion is usually short and mild. There is generally a feeling of slight malaise, headache, and sore throat. Coryza is rarely a prominent symptom, but sneezing occurs in a fair proportion of cases. Vomiting is extremely rare (1 in 326 of our cases) and as Caiger points out, its occurrence in a doubtful case is strongly suggestive of the disease not being rubeola. One symptom, however, which has been noticed by several observers, but on which we think sufficient emphasis has not been laid, is the presence of adenitis, occasionally as long as 48 hours or more, before the appearance of the eruption (70 per cent. of our cases). The glands affected are nearly always the posterior auricular, more rarely the occipital, and occasionally the upper part of the concatenate chain. Even in the absence of any palpable enlargement the patient often complains of "stiff neck," and tenderness is elicited on pressure over the upper part of the sterno-mastoid muscles.

In connexion with the adenitis the following points are of interest—viz., that it is usually sufficiently noticeable to call for remark from the patient and that the tenderness is out of all proportion to the amount of the swelling. The enlargement usually subsides with the disappearance of the rash, but in a certain proportion of cases may persist for some days after the eruption has completely faded.

The eruption.—The rash may assume one of three types: (1) the typical rubeola, (2) the morbilliform, or (3) the scarlatiniform.

1. *The typical rubeola type.*—The characteristic rubeola rash presents the following features. It appears first on the face in small, discrete, rose-red, slightly raised papules, then spreads to the trunk and later to the limbs. The legs occasionally and more rarely the arms are unaffected, but on the other hand the rash may be found on the palms of the hands and the soles of the feet, though this is not so frequent as in morbilli. As new areas are involved there is gradual fading of the rash on the parts first attacked, but as the eruption persists for a shorter time on the extremities than on the face and trunk, there is a time when it is universally present and of uniform colour. It is during the time of gradual fading of the rash on the face and trunk that there is a tendency for the papules to coalesce and give rise to an erythematous appearance closely simulating a scarlatiniform eruption. The punctate element is, however, lacking and the rash does not persist in the groins, axillæ, and flexures of the elbows as is usually the case in scarlet fever.

The total duration of the eruption is usually about 72 hours, rarely longer than 96 hours.

2. *The morbilliform type.*—This type of rash usually occurs in those cases where the eruption is very intense. It most closely resembles measles on the face and trunk, but is not so definitely raised and has a distinctly pinkish tinge as compared with the dusky red of morbilli. On the extremities the typical rubeolar rash is generally present, but chief reliance in diagnosis in these cases is to be placed on the absence or presence of Koplik's spots.

3. *The scarlatiniform type.*—The rash may from the onset appear as a more or less erythematous eruption, especially on the trunk. On close examination, however, the areas of unaffected skin are more numerous than in scarlet fever, circumoral pallor is not so frequently observed, and additional help is afforded by the character of the tongue and the absence of the disproportionately rapid pulse-rate, so frequent in this latter disease. It may be noted that the morbilliform type of rash frequently assumes the scarlatiniform type on the second day of the eruption.

The mouth.—The tongue is generally only slightly furred in contrast to the thickly furred tongue of measles or scarlet fever in the early stage. The tonsils, fauces, and soft palate are usually only slightly affected. On the soft palate a macular eruption is not infrequently present which occasionally involves the hard palate, but, as a rule, the sharp line of demarcation between the two is rather noticeable, due in many cases to the hard palate appearing paler than normal. On the soft palate we have on several occasions noticed a fine vesicular eruption in which cases the background appears intensely red. On the buccal mucous membrane a few discrete pink papules may sometimes be seen resembling those found on the cutaneous surface, but nothing in the nature of Koplik's spots is ever observed. We have, however, noticed small yellowish plaques usually on the mucous membrane behind the last molar teeth of the lower jaw, to which Dr. Sidney Phillips has directed our attention, but as these are also occasionally present in morbilli and scarlet fever they are of little value in diagnosis.

The temperature.—This is slightly raised from one to two degrees at the onset of the eruption, but in nearly all cases falls to normal within 48 hours. It is usually highest on the first day of the appearance of the rash, but occasionally may reach its maximum on the second day, never later. The highest temperatures of which we have records are 104·2° in a woman aged 23 years, and 104·6° in a man aged 33 years, but in over 450 consecutive cases we can only find temperatures of 103° and over in 14.

Pulse and respiration.—In neither of these is there anything noticeable. Both are raised proportionately to the rise of temperature.

Desquamation.—In our experience desquamation is of very rare occurrence, is usually limited to the face and chest, and is of a fine "branny" character.

As regards the infectivity of rubeola experience at this hospital bears out Goodall's and Corbin's views that it is only slight and probably only lasts for a very short period, as the disease is extremely rarely contracted here by patients convalescing from morbilli or by nurses.

We have been unable to differentiate from among the admissions of scarlet fever, morbilli, and rubeola any cases of the so-called "fourth disease" described by Dukes. If this disease were an entity it would follow that from time to time cases suffering from it would be sent up to this hospital, and being diagnosed probably either as scarlet fever or rubeola would be admitted into the corresponding ward. The natural result to be expected would be that either these patients would themselves develop scarlet fever or rubeola, as the case might be, or give rise to an epidemic in the ward of "fourth disease." We have failed to observe any such result and in fact we have been unable to find in the case notes of scarlet fever or rubeola any records of "relapses" or other phenomena which would lead one to think that an epidemic of "fourth disease" had arisen in the wards without being recognised as such.

It is often difficult to obtain an accurate account from patients of any exanthems from which they have suffered in the past, but during the last year, out of 113 admissions into the measles wards we have only been able to get a history of morbilli in 49, scarlet fever in 8, and rubeola in 5. If this may be taken as a fair average it would give annually a large number of totally unprotected individuals amongst whom would be a fruitful soil for the implantation of the virus of another exanthem.

The principal conditions from which rubeola has to be diagnosed are: (1) prodromal rashes, (2) other exanthems, (3) influenza and diphtheria with eruption, (4) specific rashes, (5) drug and toxic rashes, and (6) skin diseases.

1. *Prodromal rashes.*—These occur usually in measles, chicken-pox, and small-pox. They are characterised by their irregular distribution and by their ephemeral nature.

2. *Other exanthems.*—The principal points of difference have already been alluded to, but to summarise one may say that they are: (*a*) From morbilli the absence of Koplik's spots, and of the acute discomfort, coryza, and cough so commonly associated with this disease; the brighter colour, the finer texture, and shorter duration of the rash; and the comparatively clean tongue. (*b*) From scarlet fever the mildness of the initial symptoms, and in particular the absence of vomiting; the moderate rise of temperature and the absence of any abnormal increase of the pulse-rate, and in the rash the lack of any punctate element. In scarlet fever sudamina are of frequent occurrence, which is not the case in rubeola. Moreover, in the former disease the dirty tongue, cleaning at the edges and gradually peeling, is quite characteristic.

3. *Influenza and diphtheria.*—Rashes in these diseases are rare. In the former the more acute prodromal symptoms, especially backache, the gastric and respiratory complications, and the possibility of a prevailing epidemic, serve to distinguish it from rubeola. In diphtheria the presence of Klebs-Loeffler bacillus clears up the diagnosis.

4. *Specific rashes.*—In these the probable presence of the initial lesion, the general glandular enlargement and the character of the sore-throat, together with the history of the case, are sufficiently suggestive.

5. *Toxic and drug rashes.*—The former of these mostly arise from the consumption of shell-fish, shrimps, fruit, and tinned foods. Of drugs that give rise to eruptions, belladonna, quinine, copaiba, the salicylic compounds, antipyrin, chloral, potassium iodide, veronal, and mercury are the more important. The true causal agent is, however, more liable to be overlooked in those occasional cases in which a rash is produced by some ingredient of a patent medicine. We have recently had two cases resulting from a somewhat widely advertised and illustrated panacea for all forms of backache, in which the eruption produced somewhat resembled at first sight a rubeola rash. This nostrum, according to Colbeck and Chaplin, contains some resin-like substance, probably copaiba. As probably also toxic in character may be regarded those rashes which occasionally arise after operations. We have recently seen two cases that may be placed in this category, both occurring after removal of the thyroid gland. Enemata and antitoxin also occasionally produce rashes. In all these cases one has to place reliance on the history, and in toxic rashes gastro-intestinal symptoms are often present. The rashes produced are often pleomorphic in character and capricious in distribution. With regard to septic rashes, of these the most important are associated with "drain throat" or arise in the puerperium. In these the antecedent condition and the greater constitutional disturbance give a clue to the diagnosis. The rash is irregular in its appearance and course, and the parts of the body are not involved in the definite sequence in which they are in rubeola.

6. *Skin diseases.*—Of these, we have seen instances of erythema multiforme and pityriasis roseola. In the latter the not uncommon association of stiff-neck with a moderate rise of temperature at the onset of the eruption is specially misleading, but the fact that the rash does not usually commence on the face, that it persists for some time, and that there is often a herald patch, is of assistance in forming an opinion.

We are indebted to Dr. Sidney Phillips and Dr. William Hunter for their kindness in permitting us to use the notes of their cases.

THE CHILD-STUDY SOCIETY OF LONDON.—The Child-Study Society, London, has arranged to hold lectures and discussions during the months of October, November, and December. The subject put down for Nov. 24th, "The Philosophy of Boys' Games," by Mr. Felix Clay (Dr. James Kerr in the chair), should lead to an interesting discussion. Further information may be obtained from the Honorary Secretary, 90, Buckingham Palace-road, London, S.W.

STOVAINE:

ITS USE IN THE TREATMENT OF SHOCK, ETC., IN INJURIES OF THE LOWER EXTREMITIES.

BY GEORGE THOM, M.R.C.S. ENG., L.R.C.P. LOND.,
RESIDENT SURGEON TO THE KASR-EL-AINI HOSPITAL, CAIRO.

THE many publications on the subject of the use of stovaine apparently disregard a very valuable addition to the usual means of combating shock due to severe injuries of the lower extremities. At the Kasr-el-Aini Hospital the admissions for such accidents are very numerous. The crowded streets, the native's disregard of "the rules of the road," and the prevalence of ophthalmia combine to cause the frequent occurrence of tramway, carriage, and similar accidents. Crushed legs of varying degrees are the frequent results. On arrival at the hospital shock is always a marked feature. The police regulations insist on the patients being removed to the nearest police-station, where a *procès verbal* is taken and a report by the police doctor made on the injuries before removal to the hospital. This delay must necessarily add to the shock already present. Restlessness, a symptom of both shock and hæmorrhage, when every movement causes painful contractions of the severed muscles and crepitus of bones, adds to the gravity of the patient's condition unless immediate steps be taken for its alleviation.

At this hospital—where every operation in which low spinal analgesia suffices, stovaine or some similar preparation is used—it is now the general rule to inject a patient suffering from any very severe injuries to the lower extremity as soon after his arrival as possible. The injection is given before removal of clothes, emergency dressings, or splints to alleviate pain during these procedures and in the subsequent examination of the injuries. The preparation of stovaine used is that prepared by Poulen frères—stovaine Billon: borate d'epirenane, 0·00013; stovaine, 0·04; chlorure de sodium, 0·0011 (ampoule, 2 c.c.).

The immediate improvement after injection is very noticeable. Pain and restlessness disappear. The pulse improves rapidly, the colour returns, and the patient's distress diminishes. Thus all the symptoms of shock are alleviated or abolished. During the subsequent operative procedures the patient is encouraged to drink some brandy or other stimulant, so obviating the necessity of giving rectal salines, which may not be retained, or incurring the risks associated with intravenous injections. The operation is performed without that undue haste so often necessary in cases of severe collapse with general anæsthesia. The delay with its associated risks of sepsis and hæmorrhage awaiting the rally of a profoundly collapsed patient, in whom a general anæsthetic would be inadvisable, is practically abolished.

Post-operative shock in these patients is also greatly diminished, both in intensity and duration, as for many hours after the operation pain and restlessness are absent in nearly every case. The absence of nausea and sickness relieves the patient of an additional cause of collapse and enables the continuance of stimulant treatment by the mouth.

Anæsthesia is apparently of longer duration in these cases than in ordinary operative work, as, though the necessary preparation may take half an hour or more, no case has required a second injection for the completion of the operation, though in one case mentioned below a second injection was given later for the return of restlessness. Stovaine certainly has a general anæsthetic effect in addition to the local one, as though I personally always had a horror of the patient realising his condition and what was being done, especially the noise of sawing of bones, of instruments being used, &c., I find that, though able to carry on a conversation, he does not realise their association with himself, and no trouble from such cause has ever arisen.

A few illustrative cases will show the type in which stovaine has been of great assistance:—

CASE 1.—A native boy, aged 8 years; both legs crushed off at the middle of the tibiæ by a tram. The patient suffering from profound shock, pulseless, skin cold and clammy, screaming loudly and throwing himself about, so that with difficulty he was retained on the stretcher. Stovaine Billon, 1 c.c., injected at once into the third lumbar space. Immediate improvement of condition. Double amputation at the site of election performed. Twenty-four hours later sitting up complaining of slight headache. Recovery uneventful.

CASE 2.—A native, aged 25 years. A tram accident, causing severe crush of both legs, necessitating supra-condylar amputation of the left leg and amputation at the site of election of the right leg. Stovaine Billon, 2 c.c., injected. No post-operative shock; rapid and complete recovery.

CASE 3.—A Greek boy, aged 18 years. A tram accident. Left innominate bone crushed, practically severing the left hindquarter; the right thigh crushed off at its middle. The injury was inoperable and the patient was dying. Stovaine Billon, 2 c.c., injected to relieve his agony and on account of his desire to see his relatives before he died. Though immediate death could only have been expected in his condition the patient lived for 14 hours, quiet and comfortable, and conversing rationally with his parents and friends. He died without pain mainly from intra-abdominal hæmorrhage.

CASE 4.—A native girl, aged 11 years. A tram accident, the wheels passing over the left ankle, severing the foot and through the right knee-joint, lacerating the muscles to the upper third of the thigh. Injected 1·5 c.c. immediately on admission, though unconscious, pallid, and pulseless from hæmorrhage and shock—practically dead. Intravenous injection with brandy and adrenalin was given at the same time. Consciousness returned in about 20 minutes. Owing to the oozing of blood from the lacerated thigh and the impossibility of controlling it amputation (right subtrochanteric) and at the same time removal of the left foot was decided to be necessary, in spite of the patient's hopeless condition. She drank stimulants freely during the operation, and six hours later showed much improvement in condition, which she maintained for 30 hours. She then became delirious (temperature 40°C.), and died 48 hours after admission from acute septicæmia due to gangrene of the lacerated skin and muscle flaps which unfortunately had to be employed. There were no additional signs of shock following the operation.

The foregoing case and the previous one to it (Cases 3 and 4) are the only cases of death to record since the employment of stovaine as described.

CASE 5.—A native girl, aged 8 years. A tram accident, the left leg and foot being crushed longitudinally from the mid-tibial region. The patient was suffering from profound shock and hæmorrhage, and was pulseless and unconscious. Stovaine Billon, 1 c.c., injected in addition to other routine treatment for shock. Though the patient's condition was apparently hopeless, half an hour later she had so far improved that amputation at the site of election was performed. Consciousness returned soon after injection. During the operation she was encouraged to drink brandy-and-water, and immediately after the operation her condition caused no anxiety. Four hours later the pulse again failed and restlessness intervened. A second injection of 1 c.c. was given. The patient soon went to sleep, all signs of shock disappeared, and recovery was uneventful.

An interesting point was manifested by the second injection in Case 5. The cerebro-spinal fluid tension was low when first tapped, but on the second introduction of the needle the fluid spouted out in a forcible stream. The relief of tension thus may account in part for the quietening of the patient. This feature also suggests the re-introduction of the needle after completion of the ordinary operation cases, so relieving tension and withdrawing any solution possibly unabsorbed, and so obviating or diminishing the toxic effects, such as headache, pains in limbs and back, complained of in varying degrees by about 60 per cent. of patients. To the present time there have not been a sufficient number treated in this way to make any certainty of this point.

Many similar cases might be quoted in which the use of stovaine has shown its undoubted value in the relief of immediate shock, previous to and during the operation and in the marked diminution of post-operative shock. Several of these patients were, on admission, so collapsed that the administration of a general anæsthetic and operative interference would have been out of the question. A dangerous delay awaiting their rally must necessarily have ensued under any other form of treatment.

I should like also to mention the obvious advantages of stovaine in the treatment of cases of fractures of the lower extremity in which an anæsthetic is necessary. The possibility of struggling during the second stage of general anæsthesia and of attempted movement during recovery are always a serious consideration in their administration. With stovaine a fracture may be put up without these risks. The patient relieved of pain understands what is being done, whilst his inability to move prevents the possibility of a plaster being broken or bandages loosened—accidents which so frequently occur during recovery from general anæsthesia. Another great advantage, even in hospital practice, is the limitation of the number of skilled assistants necessary.

Finally. I wish to express my thanks to Mr. Frank C. Madden and Mr. O. Richards, under whose care the treatment of these cases was conducted, for permission to publish this paper.

THE TORQUAY MEDICAL CHARITIES.—As a result of the recent combined Friendly Societies' Fête, which was held in Torquay, the sum of £121 has been distributed amongst the medical charities of that town.

Reviews and Notices of Books.

Dislocations and Joint Fractures. By FREDERICK J. COTTON, A.M., M.D., Assistant Surgeon to the Boston City Hospital. With 1201 illustrations, 830 being from drawings by the author. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 654. Price 25*s.*

THE book was originally planned as a treatise on dislocations, but a consideration of the fact that dislocations do not present themselves to us as such, but rather as injuries to or near joints, has led the author to write of these injuries considered together. The great number and value of the observations which the use of X ray photography has accumulated have placed us in a position in which our methods, although they must still be influenced by clinical records, do not necessarily follow the fashion of preceding generations. The work of Dr. Cotton is largely personal, and although a few of his conclusions as to treatment are assailable, in the main he has presented the doctrines of the developed knowledge of the day.

The author begins with an introduction in which he discusses general questions, and he then passes to the detailed consideration of joint fractures and dislocations in a regional arrangement in 35 chapters. On the question of the routine use of X rays he is very clear in disclaiming the necessity for a skiagraph as a preliminary to the treatment of fractures in general, and states that the time for the X ray picture is after and not before reduction. In this we are disposed to agree with him, as the cases in which an accurate diagnosis is essential to reduction of gross displacement are limited, and in the great majority of cases a properly trained surgeon can make his diagnosis, so far as practical details go, without the help of the X rays. Although the X rays, in the author's opinion, should not be used in place of skilled manipulation for diagnosis, or as the arbiter of end results, he considers their use to be proper for a record of the case and necessary to confirm the diagnosis, and more especially check the treatment. Malposition if recognised within a fortnight is usually amenable to correction by handling, but if it cannot be so reduced it may require an open operation and an X ray photograph to review the result.

An adequate space is devoted to the consideration of luxations and fractures of the cervical region of the spine, and the differential diagnosis of injuries below the axis by means of "cord lesion" is fully considered. This part, like the rest of the work, is illustrated by drawings made by the author from actual cases, which are of value apart from their use in illustration of the text, as they exhibit very clearly the attitudes adopted by individuals with spinal injury, sometimes the only determining sign in a difficult diagnosis. As a rule, the author describes in each section only that mode of treatment which has proved in his own hands to be the most successful, and he does not discuss at any length the various alternative methods. For practical purposes this is probably an advantage, and we confess that the author gives us the impression that he is the possessor of much practical common sense and sound judgment. In the treatment of fractures of the humerus above the elbow-joint, in which it is difficult to preserve the straight long axis of the arm, and which on this account is often treated on a straight splint, the author prefers the Osgood-Penhallow splint, which corrects the backward displacement and overlap very effectually, deformities which if allowed to persist are much more serious than a slight "gun-stock" arm. These are considerations entirely apart from the practical inconvenience of the straight splint and the awkwardness of a possible ankylosis of the elbow at or near the useless position of full extension. Mediocarpal injuries are not forgotten, and some very practical hints are given to assist in the important differentiation of fracture of carpal bones from sprains of the wrist.

Dislocations of the hip are classified into posterior and anterior forms, the matter of first importance being whether the head of the femur has escaped so as to lie behind or in front of the plane of the Y ligament. The very irregular forms where the strong ligaments are torn loose, allowing the femoral head to take any position, and "central luxation of the hip," in which fracture of the pelvis at the acetabulum permits the entrance of the femoral head into the cavity of the pelvis, are separately considered. Reduction is by the direct manipulative methods of Allis, failing which the circumduction methods of Bigelow are to be tried, and in the last resort open operation is to be preferred to the older methods involving great force. Fractures of the neck of the femur are very ably and systematically considered, and the many expedients for maintaining the fragments in close apposition are well illustrated and explained. A chapter is devoted to fracture of the os calcis, the treatment of which resolves itself into the question of determining which cases call for reduction and which should be allowed to consolidate without interference. The methods of drawing down the heel by the help of a spindle thrust through the skin in front of the tendo Achillis and of reducing the width of the injured heel by blows from a mallet are novel and striking, but in the author's hands apparently productive of satisfactory results.

The book is well bound, well printed, and well illustrated by drawings, diagrams, and photographs. It is a pity that the plan of reinforcing his X ray photographs by carefully drawn outlines, which the author has adopted in many parts of the work, has not been adhered to throughout. The book is one which would be of service in the hands of consultant, casualty surgeon, and general practitioner alike, for they will find in it much to assist and guide them, and very little with which to quarrel.

Physical Chemistry: its Bearing on Biology and Medicine. By JAMES C. PHILIP, M.A., Ph.D., D.Sc., Assistant Professor in the Department of Chemistry, Imperial College of Science and Technology, London. London: Edward Arnold. 1910. Pp. 312. Price 7*s.* 6*d.* net.

ONE of the most hopeful signs of progress in the recent advances in certain physiological as well as in pathological processes has been the application of the conceptions and methods of physical chemistry to the elucidation of these problems. It seems all the more imperative, therefore, that students of biology and of medicine should be acquainted with the underlying principles of these physico-chemical methods. Unfortunately, not much attention is given, by the medical student at least, to these methods.

This book originated in a course delivered to biological students at the University of London in 1909. In the treatment of his subject the author assumes on the part of the student an ordinary acquaintance with physics and chemistry, and he has avoided as far as possible the use of mathematics. Physical chemistry has recently busied itself with new methods for the study of the phenomena exhibited by solutions, and as there is a close analogy existing between the behaviour of solutions and that of gases the author begins with a terse but clear description of certain features which characterise the gaseous state, and also of various theories bearing on the nature of gases, such as the kinetic theory of gases, Avogadro's hypothesis, and the static diffusion of carbon dioxide. The last subject in its biological applications is illustrated by the gas exchange between the atmosphere and the assimilating cells of a

leaf, which in some respects resembles a multi-perforate diaphragm.

The absorption of gases by liquids is next dealt with. The solubility of gases in salt solution leads to a consideration of the absorption of oxygen and other gases by the blood. Two chapters are devoted to the very important subject of diffusion and osmotic pressures. In each case the resulting movement may be regarded as due to a pressure. The importance of semi-permeable membranes is now well recognised, and the author illustrates their biological importance by experiments on the semi-permeable covering of barley grains — a membrane which is not penetrated by sulphuric acid. A wheat grain may be steeped in a solution of copper sulphate and so any adherent fungus spores may be destroyed without affecting the vitality of the seed itself. Isotonic and hypertonic solutions are fully considered, and the part played by the latter as an osmotic stimulus in the artificial parthenogenesis of the unfertilised eggs of a sea-urchin by Loeb is mentioned.

The action of semi-permeable membrane is considered, and this naturally leads to the consideration of the permeability of living membranes, including root hairs, spirogyra cells, the behaviour of organic dye-stuffs, and Overton's theory of lipoids—such as cholesterol and lecithin—in plasmatic membranes, a theory which has recently been criticised adversely by Ruhland. The difficulties of a purely physical theory are pointed out and discussed. The relations between osmotic pressure and freezing point and molecular weight is fully gone into, together with their biological applications. The apparatus of Beckmann for determining the freezing point is now much used in hospitals in connexion with urine. The author, however, deals more fully with the freezing point method for the study of the osmotic pressure of the blood from different animals. The freezing point of mammalian blood does not vary much from one species to another. The freezing-point of urine, however, even in a healthy person, varies within wide limits. In all invertebrate marine animals the freezing point of the blood, or body fluid, is the same as that of the water in which they live.

The behaviour of salts, acids, bases in aqueous solution, leads necessarily to a consideration of the principles of dissociation. Three chapters are devoted to the all-important subjects of colloidal solutions, the separation of colloids from these solutions, and adsorption. There is included an account of the Ultra-microscope, the colloid nature of enzymes, toxins and antitoxins, and the phenomena of agglutination. The last two chapters deal with the law of mass action and the velocity of chemical reaction, including catalysis and enzymatic action.

The subject-matter is excellent and the descriptions are both clear and concise. The work should prove most useful both to biologists and physiologists. There is an excellent subject index, as well as an "author index," and numerous references to original papers.

Medical Gynecology. By SAMUEL WYLLIS BANDLER, M.D., Adjunct Professor of Diseases of Women, New York Post-Graduate School of Medicine and Hospital. Second edition, revised. With original illustrations. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 698. Price 21*s*.

THIS book has apparently met with a favourable reception in America, and a second edition has been called for. It would, therefore, seem to fulfil a want on the part of American students or practitioners. We cannot predict for it any similar success in this country. The author has carried out a revision and has incorporated in this edition an account of Head's work on disturbances of sensation associated with visceral disease. This is not quite the same thing as "Head zones," a somewhat unfortunate expression which he employs. We think it is a pity that Dr. Bandler has not consulted Dr. Head's original articles, but has apparently taken his acquaintance with them from the writings of Elsburg and Neuhof; in important works of this description the original articles should certainly be referred to.

The book contains a very large amount of repetition, of which a good example is to be seen in the account of gonorrhœa and its various sequelæ. In the section on gonorrhœa in adults all the inflammatory lesions which may arise in the course of the disease are described, and then they are again described in the various sections dealing with diseases of the different organs. Under the heading of endocervicitis there is a statement with which we entirely disagree—namely, that the two symptoms of endocervicitis are a mucoid discharge and the pain due to the involvement of the cellular connective tissue, in other words to parametritis. The author brings forward no proof in support of his statement that endocervicitis usually results in parametritis; in our experience it does not, and therefore we do not consider that pain due to this cause is at all a common symptom of so-called endocervicitis. This confusion of symptoms due to two different conditions is characteristic of the author's habit of writing, and for this reason the book is not one we can recommend.

Dr. Bandler is in favour of bimanual massage in chronic conditions of the pelvic organs, a mode of treatment which is quite out of favour in this country and which is at any rate not practised by any gynæcologist of repute at the present day. In the same way the treatment of pelvic affections by electricity, although it is true it is carried out by some specialists in the application of electricity, is not practised to any extent by recognised gynæcologists, and for this reason the English reader will have no sympathy with the large amount of space the author devotes to this method of treatment.

A Textbook of Obstetrics. By BARTON COOKE HIRST, M.D., Professor of Obstetrics in the University of Pennsylvania. New (sixth) edition, revised and enlarged. With 847 illustrations, 43 coloured. London and Philadelphia: W. B. Saunders Company. Pp. 992. Price 21*s*. net.

IN this, the sixth edition of his well-known text-book, Professor Hirst has made numerous additions to the sections on operations. He maintains, and in our view quite rightly, that all the diseases of women must be considered in relation to the chief act in woman's history, child-bearing. The vast majority of these diseases are consequences, and all are possible complications, of that process. Therefore, the obstetrician should also be a gynæcologist. With this argument we quite agree, and indeed in this country it has long been the custom that obstetric physicians should also practise gynæcology and perform gynæcological operations. But when the author maintains that it is illogical to recommend various gynæcological operations to the student and then in a text-book on obstetrics not to tell him anything about them, we cannot agree. That is to say, the student should of course be told all about these operations, but in our opinion this is best done in a book devoted to gynæcology, such a work, for example, as Professor Hirst's own excellent book on diseases of women. An attempt such as has been made in this work to include a description of all the gynæcological operations recommended leads to an over-bulky volume, and further, it is impossible to describe them so adequately or so well as can be done in a separate book. For this reason we do not think that the author has been well advised in adding to his book the descriptions of all these various operations. Nor, indeed, he has limited his descriptions to operations the

result of childbirth; for example, this term cannot be applied to the operation for complete atresia of the vagina, to which some three pages are devoted.

This new edition has been increased in size by many pages and 80 illustrations have been added, giving it unwieldy proportions. The section on the application of the forceps is disappointing; the author figures an old model of Tarnier's forceps, and tells his readers that this represents the latest and best type of axis-traction forceps. He says nothing of the work done by the late Milne Murray, and the very excellent patterns of axis-traction forceps he devised, much better and more efficient than those of Tarnier. Professor Hirst does not, however, use axis-traction forceps properly, since he apparently takes off the traction rods when the head is in the cavity and makes traction on the handles—an entirely faulty procedure, and one which converts even the best pair of axis-traction forceps into a very bad pair of ordinary forceps. The grip suggested for the purpose of making axis traction with a pair of Simpson's forceps is not nearly as satisfactory as that recommended by Galabin, and we can recommend Professor Hirst to try the latter method in place of his. He is of opinion that pubiotomy, or hebotomy as he prefers to call it, will become obsolete and does not approve of the operation. In this he will be supported by the opinion of nearly all English obstetricians, but at the same time he does not describe the best methods of performing the operation, nor does he give his readers the latest and best results which have been obtained; they are, therefore, not in a position to form an independent judgment. It is a pity when drawings are taken from other works that they are not taken from the originals. Thus, for example, Fig. 464 from Pinard and Varnier's Atlas does not in reality represent the original, since in the latter the line of section does not pass through the cervical canal. This may seem a small matter, but accuracy in things of this kind is important, and it should be stated that the drawing is really diagrammatic. It is odd when the two instruments are both mentioned that anyone should recommend decapitation with a Braun's blunt hook rather than with Ramsbotham's sharp hook, but it is so in the present case.

There is a great deal in this book of value, and it is undoubtedly a useful and fairly complete text-book; there are, however, minor inaccuracies and omissions which detract to some extent from its value. As we have already said, we think the attempt made to convert it in part into a text-book of gynæcology as well as one of obstetrics is a mistake.

Fractures and Separated Epiphyses. By ALBERT J. WALTON, F.R.C.S. Eng., M.S., M.B., B.Sc. Lond., L.R.C.P. Lond., Surgical Registrar, London Hospital. London: Edward Arnold. 1910. Pp. 283. Price 10*s.* 6*d.* net.

THE book under review is addressed to the students of the London Hospital and deals with all the varieties of fracture that are likely to come under their notice. The first three chapters are given over to general considerations, and the remaining 13 deal with the fractures of particular bones. The author's aim has been to indicate the smaller details of treatment, so that "anyone having no special previous knowledge of this branch of surgery might find this book an aid to him in the practical treat-treatment of any fracture." In this he has succeeded very well. At the same time he has thought it advisable to describe in their main outlines the more complex methods, including open operation, which may at times be necessary. Those who undertake these operations will no doubt prefer to consult original descriptions for help and guidance, but, nevertheless, the author's descriptions will prove of help to students and house surgeons assisting at such operations.

The author is not an extremist. He prefers the *via media* between the method of complete and continuous immobilisation and the ambulatory method, and advocates the judicious use of massage and passive movements in combination with retentive apparatus, the friction and movement being regarded as the adjunct to the splint and not its substitute. In regard to amputation for fracture, he holds strongly conservative opinions. Thorough antiseptic treatment of compound fractures saves many a limb, and the amputation which may be afterwards required leaves a "soft, supple, and painless stump" instead of the "painful irregular stump of a primary amputation." Sufficient information is given of recent important advances in the surgery of fractures, especially in regard to injuries of nerves and bone grafting. The book is well illustrated with radiographs, and contains many clearly executed diagrams depicting the methods of application of the splints in common use.

Read without regard to the context, some of the author's sentences are unfortunate. An instance appears on p. 164, beginning the third paragraph: "If the neck be fractured, the arm should be put up in a position of flexion, &c." Viewed as a students' book, and it claims to be no more, it can be well recommended both on account of the practical details it contains and the sound common sense which characterises it.

Serum Diagnosis of Syphilis and the Butyric Acid Test for Syphilis. By HIDEYO NOGUCHI, M.D., M.Sc., Associate Member of the Rockefeller Institute for Medical Research, New York. London and Philadelphia: J. B. Lippincott Company. 1910. Pp. 173.

ONE of the most remarkable advances in modern medical practice has been the discovery of chemical and bio-chemical tests for the recognition of certain diseases. Roughly, these tests may be divided into the purely chemical, of which Ehrlich's diazo reaction and Cammidge's test for pancreatic disease may be taken as types, and the tests dependent on reactions involving living organisms and their specific products, as seen in the test for enteric fever associated with the name of Widal, as well as in the precipitin tests used in medico-legal investigations. The reaction found by Wassermann in the blood of syphilitics seemed at first likely to fall into the latter class, but further research would seem to show that it is rather an example of the former, since it is now known that the syphilitic antigen may be replaced by material derived from a source uninfected by this disease. Many variations of the test have been proposed, but all of them remain somewhat complicated and unfit for ordinary clinical use, involving as they do procedures which can scarcely be carried out except in a well-equipped laboratory.

In the volume before us Dr. Noguchi explains the simplified method which he himself has devised for carrying out the test and which he hopes may facilitate its general use. It consists in employing small pieces of filter-paper impregnated with the antigen and the amboceptor respectively for addition to the fluid to be tested and to the control. He also points out that an incubator is not indispensable, as the warmth required may be obtained by carrying the tubes in the waistcoat pocket. In spite of this ingenious arrangement we doubt whether the test can be brought into general clinical use, in view of the existence of doubtful and incomplete reactions in many cases. These can only be interpreted by an expert, and we are inclined to think that in inexpert hands the test would lead to error rather than to illumination. Nevertheless, the book is well worthy of perusal as it contains a very clear account of the phenomena on which the Wassermann test depends, illustrated by coloured diagrams; and the peculiar quantitative relations of complement and amboceptor in the process of hæmolysis are well shown.

The last chapter is devoted to an account of a second chemical test for syphilis, devised by the author, depending on the existence of an increased amount of globulin in the cerebro-spinal fluid of syphilitic patients. The procedure consists in mixing two parts of the cerebro-spinal fluid with five parts of a 10 per cent. solution of butyric acid, heating the mixture, and then adding one part of normal caustic soda solution, and boiling. A flocculent precipitate of globulin is thus thrown down, the greater the amount present the shorter being the time required for the reaction. An increased globulin content may be present in cases of meningeal inflammation, but such can be readily distinguished from syphilis. Dr. Noguchi thinks that the test is of considerable value for the recognition of syphilitic and para-syphilitic conditions, and gives tables showing the correspondence of the results obtained by means of this test and of the Wassermann reaction. The book ends with an exhaustive bibliography.

LIBRARY TABLE.

Malaria and Mosquitoes. By Major R. J. BLACKHAM, R.A.M.C., Divisional Sanitary Officer at Peshawar. With a preface by Lieutenant-General Sir JAMES WILLCOCKS, K.C.M.G., Commanding the First Division of the Indian Army.—This pamphlet is the reproduction in printed form of a lecture delivered by Major Blackham before the officers, non-commissioned officers, and men of the Peshawar Division with the object of instructing them how to escape the dangers arising from malaria. A concise account is given of the life-history of the anopheline mosquito and of the malarial parasite. The pamphlet contains some 15 illustrations. The mosquito is said to be the pest of the Peshawar Valley, and life there in summer is a continual campaign between the soldier and the insect. The advice given by the author is sound, and if followed up the result should be increased health as well as comfort for the troops in that region. Major Blackham is not gallant, as the following quotations will show: "In malaria, as in many of the ills of this life, it is a case of *cherchez la femme*. The male mosquito is a harmless vegetarian, but his mate is a voracious carnivora." "In cool climates the lady mosquito, instead of being braced up, becomes lethargic and either goes back to vegetarian habits or merely hibernates. In this respect she resembles some individuals of her sex on a higher plane who are harmless in temperate climates, but develop bad habits in the warmth of the tropics." "It is quite easy to distingush the innocent male anopheline from the wicked vixen, his wife." In referring to the owl midge which transmits disease in the Peshawar Valley, Major Blackham remarks "here, again, it is the ladies of the family who give all the trouble."

Anæsthesia in Dental Surgery. By THOMAS D. LUKE, M.D. R.U.I., F.R.C.S. Edin., and J. STUART ROSS, M.B. Vict., F.R.C.S. Edin. Third edition. With 27 illustrations. London: Rebman, Limited. 1910. Pp. 227. Price 6*s.*—In the third edition of his book Dr. Luke has had the coöperation of Mr. Ross, in whose hands has been placed the revision of portions of the text. The alterations, however, are not of such scope as to demand a detailed account of this edition. The book maintains its former character as a clear account of the practice of anæsthetics in connexion with dental surgery. There has been appended a short summaryof the recent attempts at legislation on behalf of the public welfare in connexion with anæsthetics, and the authors give their own views as to the desirability or otherwise of administration by those not medically qualified. Another new feature is a list of recorded fatalities under ethyl chloride. In the section devoted to the nasal administration of nitrous oxide we are disappointed at finding no allusion to Trewby's apparatus, probably the most efficient at present in use. Dr. Luke is to be congratulated on the appearance of a third edition, an evidence of the success which the concise and practical character of his manual has earned and fully deserved.

Old Continental Towns. By WILFRID M. GALLICHAN. London: T. Werner Laurie. 1910. Pp. 291. Price 6*s.* net.—Mr. Gallichan has managed in the space of some 300 pages to provide his readers with some pleasant if superficial chat about various celebrated towns. The superficiality is necessary, for he deals with such cities as Rome, Florence, Verona, Chartres, Athens, and Toledo, any one of which would afford material for a book ten times the size of the one before us, and in all there are 25 towns dealt with. Of the historic and artistic interest of all there can be no doubt, and at least two of the cities in question—namely, Cordova and Toledo—are of special interest to medical men, for it was in these towns that the lamp of medicine was kept alight by the Moors from the tenth to the twelfth centuries, when in other parts of Europe except Salerno it was nearly extinct. Cordova, too, was the birthplace of Averrhoes; and Gerard of Cremona, who translated 76 medical works from Arabic into Latin, worked at Toledo. The book is illustrated by reproductions of old prints, mostly dating from the first half of the last century, and may be recommended to anyone who wishes to get a bird's-eye view of cities steeped in historical and artistic lore.

JOURNALS.

The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. III. No. 12: July, 1910. Oxford: At the Clarendon Press. Subscription price 25*s.* per annum; single numbers, 8*s.* 6*d.* each.—The contents of this number are: 1. Ochronosis Associated with Carboluria, by A. P. Beddard. This paper contains a record of a case of ochronosis associated with the use of carbolic oil for ulceration of the legs. The relation of this condition to chronic poisoning with carbolic acid and to alkaptonuria is discussed and the various views expressed by different authorities are reviewed. 2. Bigeminy of the Ventricle and Auricular Fibrillation, by Thomas Lewis. Tracings and electro-cardiograms are reproduced to show that the ventricular bigeminy which occurs in clinical instances of auricular fibrillation, either spontaneously or in the wake of digitalis administration, is due to disturbance of the irregular series of responses to the auricle by ectopic beats arising in the ventricular musculature itself. 3. A Simple Clinical Method to Demonstrate and Measure Dysergia, by Tom A. Williams. 4. Modern English Cardio-vascular Teaching, by E. M. Brockbank. He subjects some of the conclusions of Dr. James Mackenzie and his followers to a detailed criticism, and combats the generally accepted view that the crescendo murmur of mitral stenosis is auriculo-systolic in origin. 5. The Motor Functions of the Stomach: Part I., Physiology, by Arthur F. Hertz. This is an interesting review, with bibliography of recent work, including the observations of bismuth meals by means of the X rays. 6. Some Morbid Histological Changes met with in the Lymphatic Glands, especially in connexion with the Formation of "Hæmolymph" Glands, by W. O. Meek. It appears that in pathological conditions in the human subject the occurrence of hæmolymph glands in large numbers is almost universal, and further, that every lymphatic gland is a potential hæmolymph gland. The changes observed in lymphatic glands in acute and chronic diseases, together with their histological characters, are described. Some observations on the cellular elements of the glands and on the fluid expressed from the glands are also given. The latter seemed to show that antibodies and

allied substances which occur in the blood serum are not easily demonstrable as such in the lymphoid organs in other than small amounts. 7. Critical Review: Lactic Acid in Metabolism, by J. H. Ryffel. Part II., Lactic Acid in Pathological Conditions. The conditions under which this acid may accumulate in the blood sufficiently to cause its active excretion are enumerated, and its formation in connexion with excessive muscular activity, the eclampsia of pregnancy, diminished oxidation, diabetes, and other conditions is discussed. A bibliography of 55 references is appended.

The Quarterly Journal of Microscopical Science. Edited by Sir RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM SEDGWICK, F.R.S., SYDNEY J. HICKSON, F.R.S., E. A. MINCHIN, M.A., and GILBERT C. BOURNE, D.Sc., F.R.S. With lithographic plates and text figures. London: J. and A. Churchill. New series. No. 219, vol. lv., Part 3. September, 1910. Price 10*s.* net.—The articles contained in this number are: 1. Notes on the Free Living Nematodes, by F. P. Potts, M.A., Fellow of Trinity Hall, Cambridge, with 11 text figures. (1) The Hermaphrodite Species. Mr. Potts has worked at the Sutton Broad Laboratory, Norfolk, and has particularly studied the two forms, Rhabditis gurneyi and Diplogaster maupasi. In the free-living nematodes of these groups some are bisexual; some are hermaphrodite, in which, besides the self-fertilising protandrous hermaphrodites which form the great mass of the species, there are occasional male individuals perfectly developed apparently, but taking no part in reproduction; and, lastly, some that are parthenogenetic, in which males have not been found. The description of these forms and their biology occupies the greater part of the article, but there are extended notes on hermaphroditism, both complete and partial, and on self-fertilisation. 2. Observations on Trypanoplasma Congeri: (1) The Division of the Active Form, by C. H. Martin, demonstrator of zoology, University of Glasgow, with one plate and one text figure. 3. The Development of Aplysia Punctata, by Mr. A. M. Carr Saunders and Miss Margaret Poole, with one plate and 20 text figures. The observations of these investigators were commenced by Mr. A. M. Carr Saunders at the zoological station at Naples, and have been completed by both at Oxford. The authors give a very full account of the development of the several organs of the sea mouse, illustrated by numerous figures. The article is exceedingly interesting as showing the earlier processes of cell division in the embryo and then following out the history of the structures proceeding from each cleavage cell—information which is sadly needed, not in the mollusca alone, but in many other forms of life. 4. The Relation between Light and Pigment Formation in Crenilabrus and Hippolyte, by F. W. Gamble, F.R.S., Mason Professor of Zoology, University of Birmingham, with a plate. 5. Is the Trophoblast of Hypoblastic Origin, as Assheton will have it? by A. A. W. Hubrecht, with seven text figures. Mr. Hubrecht thinks it is not. 6. The Origin and Formation of Fibrous Tissue Produced as a Reaction to Injury in Pecten Maximus as a Type of the Lamellibranchiata, by G. H. Drew, B.A., Beit Memorial Research Fellow, and W. de Morgan, F.Z.S., with a plate.

MEDICINE AND THE LAW.

Prepared or Vegetable "Lard."

IN two recent cases heard at the South-Western and Clerkenwell police courts respectively, the subject of the prosecution was the alleged sale as "lard" of vegetable preparations manufactured in imitation of lard from cocoa-nut oil. At the South-Western police court Mr. Chuter, inspector under the Battersea borough council, proved that while he was dividing, according to the prescribed practice, the article which a female witness had purchased for him at his request, the defendant who had sold it said: "This is not pure lard, it is prepared lard," and added in explanation, "It is vegetable lard"; and it was not denied that the defendant when the purchase was being made and when he was asked for "lard" made a statement to the effect that what he was selling was "prepared lard." Also under the stuff in the wrapper was a green label bearing the words, "McDoddies' Prepared Lard—a pure vegetable product." Mr. De Grey, the magistrate, seems to have had some doubts as to the decision at which he ultimately arrived, for he observed that it was an objectionable practice to describe something as lard that was not lard. Nevertheless, he gave weight to the statement made that the article sold was "prepared," and also to the presence of the label, which, in his opinion, could easily be seen, and he dismissed the summons, although he refused to allow any costs to the defendant. In the second case referred to the "lard" sold was of a similar character, and was in a wrapper which described it as "Pure Vegetable Lard," with the word "lard" in large and the word "vegetable" in small type. In this case Mr. Ricketts, appearing for the prosecution, laid stress upon the true meaning of lard as defined in the Pharmacopœia and "Encyclopædia Britannica," which, he stated, described it as prepared from "hog fat." For the defence it was argued that lard was a generic term applicable to a vegetable fat. Mr. D'Eyncourt held that the wrapper produced before him was not a sufficient disclosure to the purchaser of the nature of the article sold, and, moreover, he accepted the definition of lard as "hog's fat." He pointed out that apart from the Sale of Food and Drugs Act, under which the summons was taken out, an action would lie in such a case at common law for breach of contract, and he convicted the defendant, fining him £10, with £1 11*s.* 6*d.* costs. In comment upon these two cases it may be pointed out that, like most others of their class, they arise out of the desire to sell an article which the vendor can obtain more cheaply instead of an article which will cost him more. The wrapper with the word of qualification printed small is an old device, and the purchaser in any case derives but little protection or information from a wrapper which he or she usually does not take the trouble to read. With regard to the point as to "lard" being a generic term, it may be suggested that the honest manufacturer, having had pointed out to him by Mr. D'Eyncourt that it is not, can cease to use it and will find a generic term, and a very obvious one, at his command. He can call his compound "vegetable fat," or "prepared fat" without any likelihood of his right to do so being questioned. This, however, he is not likely to do. Such terms as "lard" and "suet" indicate the source from which the fat should be derived, and are used because purchasers want lard or suet, and ask for them, but would not purchase "vegetable fat" if that accurate description were placed conspicuously on the label. The particular implication of the word "prepared" in the first case referred to which appears to have influenced Mr. De Grey is not easy to grasp. "Prepared lard" might imply lard which had been prepared or made ready for use in some particular way, but in the ordinary use of two not very extraordinary English words it would hardly suggest to anyone that the article in question was not lard at all. It must be remembered, moreover, that the purchasers whom it is sought to protect by proceedings such as those referred to are housewives of a humble and not very highly educated class.

The Law Relating to Medical Prescriptions.

All are aware of the difficulties, financial, practical, and ethical, which have hindered the universal adoption of the practice of prescription writing, amongst which not the least is the loss of control of his patient by the medical man, which may follow from the giving of a prescription to a person who, ignorant or careless of its real significance as specifying a remedy for a particular individual, in a particular state, at a particular time, may have it dispensed more often than is necessary, or, indeed, safe, may pass it on to his friends and neighbours in a spirit of false benevolence, or may even make it a source of commercial gain. The consideration of these very real dangers involves questions as to the legal property in a prescription and the rights, if any, retained in it by its author after he has handed it to his patient. Such questions are often debated, but sometimes, we fear, without due appreciation of the points of law involved, and we have pleasure in commending to the notice of all who are interested in them an article which has been specially written for our columns, and which appears on p. 1030 of this issue. Although somewhat negative in its conclusions, it will, we trust, serve a useful purpose as a learned review of the subject in all its bearings.

THE LANCET.

LONDON: SATURDAY, OCTOBER 1, 1910.

Dentistry and School Children.

THE treatment of the teeth of our children is a matter of the first importance to the country, a fact which the revelations of the officers undertaking the medical inspection of school children have brought clearly to the knowledge of all. But if inspection has revealed the evil, the remedy has yet to be found. The problem bristles with many difficulties, and very divergent views are held as to the proper course to pursue. At the London County Council the matter is now under discussion by a committee of that body, and in order to supply a basis for deliberation and a standard for comparison Mr. R. BLAIR, education officer to the Council, has brought to public attention the methods being adopted in certain parts of the German Empire and their results. Those adopted in Strasburg and Berlin are referred to especially in Mr. BLAIR'S excellent report on "School Dentistry in Germany," and there can be no doubt that our great cities, and not only London, have much to learn from our German neighbours, though direct imitation in every respect would not be generally thought wise. In Strasburg a school dental clinic was established in 1902, and since its foundation 26,164 children have been examined, the work including 42,457 fillings and 45,285 extractions. The officials of the clinic include as honorary director Professor JESSEN, the veritable pioneer of the work in that city, two paid dental surgeons (ladies), a clerk, and two assistants. The paid dental surgeons are State officials, are engaged for full time, and are not allowed to undertake private practice. The treatment is quite free and tooth-brushes are given to the patients. The whole expense of the clinic is therefore borne by the municipal authority. In Berlin, where there are 230,000 children, the work is conducted on independent lines, although it is aided by the local educational authority. The Imperial law of 1893 provides for compulsory insurance against unemployment through physical disablement, and every wage-earner whose annual income does not exceed £100 must, after the age of 16, contribute a fixed amount weekly to the national insurance fund. The law permits the local administrative authority to provide means for preventive treatment, if thereby they can save their funds. The Berlin Landes-Versicherungsanstalt has availed itself of this enactment to establish dental clinics. Two school clinics have been formed, the officer in charge of each receiving £200 per annum and the assistant officer £10 per month. To each clinic are attached a properly trained nurse and a woman clinical assistant, the stipends being respectively £60 and £36 per annum. Towards the establishment of these clinics the local educational authority has contributed £1000 towards capital expenditure and maintenance. It is considered that at least 13 clinics will be required for Berlin.

When we turn to the problem as it confronts us in London we are met with the magnitude of the task, for it is computed that there are about 600,000 children requiring treatment, the appalling amount of disease being quite unappreciated except by the dental surgeons attached to the schools or the hospitals. We take London as the example upon which to found our remarks, because of its gigantic size, and because the problem before the London County Council is acute; but the general lessons apply to any great city, though the difficulties of dealing with the admitted evil are probably more complicated in a congeries of towns like London than in any homogeneous centre, however great. To the thoughtful student of the problem the question naturally arises whether the formation of school clinics is the best method of dealing with the dental condition of the masses of children. The school clinic will only reach the children in the majority of cases after the sixth year. By this time irreparable damage has frequently been done to the child's denture, which could easily have been avoided by proper measures taken during the earlier years. To put the point in another way, the expenditure on dental treatment of 1000 children under the age of six years will give far more reaching results than a similar expenditure of time and money on 1000 children of the ages of say seven to nine years—the earlier the age at which the children are brought under observation the better. Remedial treatment, moreover, will not be of permanent benefit unless the individual knows the methods of prevention and will adopt them. If the teeth are not placed under proper environment by the adoption of prophylactic measures, caries will continue to appear. Preventive measures should be drummed into children from the very earliest age; indeed, many odontologists believe that if the simple rules of hygiene were inculcated from infancy, 90 per cent. of the caries seen at the present day would disappear. Advocates of school clinics suggest the teaching of oral cleanliness by the teachers and tooth-brush drill. Excellent as the instruction from such teachers may be, it will have little practical effect unless there is parental supervision. Preventive teaching to the child would be of far greater value if given by the parents, and the main reason why it is not given in the home is that the parents themselves are too often ignorant of the simple measures required. Again, tooth-brush drill is of little value when carried out during school hours; to be of value it must be carried out at the proper times, the most important of all being the last thing before going to rest.

If the public funds are to be utilised for dental treatment the money should be expended in such a way as to give the best results. To spend money on the teeth of the school children and to neglect the teeth of the infants is wasteful in the extreme, and education committees, where its funds are limited, would do far better for the community by concentrating its attention in the first place on its future scholars rather than its present scholars. The amount of money that will be earmarked for dental treatment is pretty sure to be insufficient to carry out the work as thoroughly as it should be done, whatever community may be in question; in London such insufficiency must be counted upon. The problem

therefore that the educational authorities have to face is how best to employ the funds available. In our opinion the problem should be approached in the following order: (1) the thorough teaching of prevention to the parents; (2) the remedial treatment of the infants; and (3) the remedial treatment of the school children. Instruction as to the prophylactic measures to be used is far and away more important than any amount of remedial treatment, and it has, too, this great advantage—that the measures to be adopted are simple in the extreme. This instruction on the care of the teeth should be systematically given in all the State schools to the parents and would-be parents, and the instructors should be properly qualified dental surgeons. An immense amount of good would be done, too, if the dental hospitals gave free popular lectures to the public. A well-organised crusade throughout the country on the importance of the teeth and the technique of their proper care would be followed in a generation by an immense improvement in the health of the nation, and, from the point of view of the combatant services, by an enormous decrease in the percentage of recruits rejected for defective teeth.

Fashion in Surgery.

WHAT the future of surgery has in store none can tell. There is, however, no little risk that in becoming accustomed as we are to a rapid progress in our ideas and methods we may from time to time mistake mere change for progress, the mere introduction of a new method for true advancement, a chance which is certainly increased by the fact that many procedures in surgery hold a place in our technique for a very brief period. When we look back on the last 50 years we can detect many cases in which a new process or a new operation has been devised and has been received by nearly, if not by all, surgeons as a great and sometimes as an epoch-marking event, and yet a few years later the novel method has become discredited and before long has dropped entirely out of use. When Sir JAMES SIMPSON introduced his method of arresting hæmorrhage by acupuncture it was thought by many, and certainly by himself, that he had devised a method which would utterly replace all other means of stopping bleeding. The size of the volume which he devoted to its description may surely be taken as some indication of the importance he attributed to his invention; but where is acupuncture now? Absolutely forgotten; many medical men of the present day would not be able to say what it is.

Coming to more recent times, we had some 13 or 14 years ago the publication of CALOT'S method of forcible reduction of angular curvature of the spine. The wonders of the new operation were proclaimed in nearly every medical periodical; pictures of the mode of carrying out the process became familiar to all readers of medical literature; the ease and safety with which the reduction was effected was dilated on; the completeness of the restoration to the normal state was demonstrated by numerous illustrations of the condition of patients before and after the marvellous operation. Where is CALOT'S method now? In the whole of this country or even in the world has the operation been performed on a single child within the last five years? Dangers undreamed of or unmentioned at the time soon made their appearance. A few sudden deaths occurred and the promised improvement in the power of walking never materialised. We acknowledge that many surgeons, even from the very first, pronounced CALOT'S forcible reduction as barbarous, unscientific, and useless; and we may perhaps mention that early in the propagation of the method we pointed out the lack of support from pathology which the method possessed. In even more recent times still we have had gastro-enterostomy put forward as a panacea for all the ills that the stomach is heir to, for pyloric stenosis, both functional and organic; for ulcer of the stomach and of the duodenum, whether involving the pylorus or not; for hæmatemesis arising from almost any cause; for dilatation of the stomach, both with and without pyloric stenosis; for malignant as well as for simple affections of the stomach; in fact, for so many conditions that the feeling naturally arose that Nature had decidedly erred in not providing the human frame with what may be called a normal gastro-enterostomy. Time, which tests all our inventions, has shown that this operation does not possess all the powers attributed to it, and at the present day probably the majority of surgeons will agree that gastro-enterostomy is seldom of permanent value unless there is definite obstruction at the pyloric opening. In most cases where no such obstruction exists the artificial orifice will soon close and the food resume its original route. It is true that in many conditions the cases were none the worse for the abnormal aperture, but that it benefited many of them is more than doubtful. We have no wish to decry the operation in suitable cases; it is of immense value in permitting the emptying of a stomach the natural outlet of which has become obstructed, and as a temporary measure it may afford relief to some other gastric and pyloric lesions, but it has fallen far from the high position it once occupied as the remedy of remedies for abnormal gastric conditions.

It is, perhaps, in relation to some of the methods of operating that fashion has the widest sway at the present time. The marvellous results of the Listerian practice when first made public to a wondering surgical world were so readily reproduced by any surgeon who chose to take the necessary care that it was not long before they came to be looked upon as almost commonplace, and when later it was found that similar results could be obtained by methods alike in principle though different in practice a tendency arose to lay stress on certain points and to regard as out of date the methods of LISTER himself. All who are well acquainted with the history of modern surgery look upon aseptic methods merely as a natural development of antiseptic surgery, not as opposed to it; and they will acknowledge that in most operations the results of antiseptic surgery cannot be surpassed. When in the summer of this year some of the members of the American Society of Surgery visited London they were surprised to find Sir WATSON CHEYNE still using strong solutions of carbolic acid in his wounds, and some of them, we believe, were inclined to regard the method they saw there employed as not representative of the best modern surgical practice. But it is by the results that surgical

methods must be judged, and we venture to think that the results of this method will compare with the most rigorous aseptic practice. Often the details of a method will be accorded an importance which is more than their due. We may take as an instance the question of the material of which ligatures should be composed. When LISTER first advocated the employment of catgut as a material for ligatures numerous writers pointed out the objections, both theoretical and practical, to the use of this substance, but time has seen a change, and many surgeons at the present time maintain that the only suitable material for a buried suture is catgut, and that silk should never be employed except for skin sutures. In this, as in so many other points, the surgeon is greater than the detail. It is certain that millions of silk sutures have been inserted in the deep tissues, and have not cut their way out, for if a suture does make its way to the surface it is probably always because it was septic. The attempt to find a ligature or suture perfect in every way has caused surgeons to employ many different substances; metallic sutures for a time received much support, though they are rarely seen now. Animal fibres of various kinds, such as kangaroo tendons and threads of the aorta of the ox, have been praised by some surgeons, and one surgeon claimed that perfection was to be found in fibres obtained from the ligamentum nuchæ of the narwhal. It is fortunate that the medical world has not fallen in with this latter recommendation, for it is to be feared that the supply would fall far short of the demand. The difficulty of rendering the hands of the surgeon aseptic led not long ago to the introduction of gloves, and in this country it is probable that the majority of surgeons employ rubber gloves in their operations, and in some hospitals that surgeon is considered to be out of date who does not employ them. Yet it is of interest to note that in many hospitals abroad, especially in Germany, there is a tendency to discard the rubber glove as needless at least, even if not actively harmful, because if the glove becomes frayed new dangers are introduced. Here, again, the surgeon is more important than his gloves. Perfect results have been and are being attained by some surgeons who, gloveless, trust to the thorough cleansing of their hands before and after operation; other surgeons obtain equally satisfactory results while wearing rubber gloves. It is possible of course for a surgeon, careless in his methods, to obtain unsatisfactory results, and whether he wears rubber gloves or not will make very little difference.

Every change is not necessarily a change for the better, and this is proved by the neglect, to which we began by drawing attention, that has fallen upon procedures once highly vaunted. By the most varied methods and the most diverse practices surgeons of the right spirit can claim results which they need not fear to compare with those of any other surgeon, for results depend much more on the surgeon himself than on the methods he happens to employ. He is the better surgeon who can so use the material with which he provides himself as to get the best results. To make success depend on the employment of a particular instrument or a special ligature is to misunderstand the problem which is set before the surgeon and to make a shibboleth of a minor point. In the future, as in the past, many innovations will be brought forward which cannot stand the test of time, but we shall be less likely to be led away by them if we examine the principle on which they are based, and if we recognise that on the right application of right principles successful surgery depends.

The Responsibility of Our Hospitals and Deaths under Anæsthetics.

THERE are many difficulties to be overcome before our hospitals escape from adverse criticism directed against their arrangements for anæsthetising patients. In the report of a recent inquest held by the City coroner upon a man who died while under the influence of ether in Guy's Hospital we find these difficulties only too well displayed. A condition of acute peritonitis following the rupture of an intestinal ulcer and associated with vomiting appears to present more than ordinarily grave aspects when an anæsthetic has to be given. That an operation was urgently required is shown by the house surgeon's remark in evidence that it gave the patient "a 1 per cent. chance." The death, which occurred before the operation could be commenced, was due to vomited material entering the air passages and causing suffocation. The report, which lies before us, does not tell us anything either concerning precautions such as the performance of preliminary lavage or of means for resuscitation such as measures which would be directed to the removal of foreign bodies from the trachea and bronchi; indeed, as the house surgeon who administered the anæsthetic intimated to the coroner that he was prepared to certify that the death was due to peritonitis, it seems possible that the true dangers which were present were not wholly appreciated.

It is not our intention, however, to dwell upon the details of this particular case, but to refer to the views which the coroner advanced in the course of the inquiry held in his court. Dr. F. J. WALDO'S wide experience lends additional weight to such pronouncements. The Departmental Committee appointed to inquire into the laws relating to coroners and the practice in coroners' courts recommended that "every death under an anæsthetic should be reported to the coroner, who, after inquiry, should determine whether it is desirable to hold an inquest or not." With the first part of this suggestion Dr. WALDO heartily agreed, since it was a well-known fact that only a small proportion of deaths under anæsthesia in private practice ever came to the notice of registrars or of coroners. With the latter part of the recommendation, however, he disagreed, since he did not think such a change in the law at all favourable to the public interest. He preferred the English open method of inquest by coroner and jury to the private inquiry as held by the procurator fiscal in Scotland into violent or unnatural deaths. Such secret investigations were, he thought, hardly favourable to a full statement of the facts with regard to so delicate a matter as that of fatal anæsthesia. He is further of opinion that "junior officers" at hospitals should not be left to administer anæsthetics in serious cases unless an expert is present, and that in all cases of death under, or due to, anæsthetics,

a necropsy should be made by an independent skilled pathologist. The City coroner pointed out that in hospitals to which a large staff of experts are attached fewer deaths had arisen since the number of expert anæsthetists there had been increased. Indeed, no one would attempt to gainsay the truth of the advantage to the patient if his case is submitted to the care of the most skilled and experienced. To sum up the difficult question of compulsory inquests. The evidence given before the Departmental Committee demonstrated that some persons whose views are worthy of attention do not hold coroners' courts and their findings as sacrosanct; indeed, they appear to regard them as mediæval in constitution and of little value in carrying out what is after all their primary function—viz., the investigation into the question whether the deceased came by his death through unnatural causes, causes provoked by himself or others, and whether the death was criminally produced. These critics admit that in spite of the constitution of such a court an experienced coroner, especially if he possesses scientific knowledge, may invest the inquiry with dignity and lead it along correct lines. The whole point is the personality of the coroner.

DR. WALDO'S suggestion that the resident staff at the hospital should not administer anæsthetics is not so simple. Experts, we are told, take years of making; they are not like poets, they must be made after birth; and if responsible practice in the production of anæsthesia is to be taken wholly from the juniors they will lose their chances of learning this most important branch of their profession during their hospital career. Incidentally, the experts themselves must under such conditions become extinct in the near future. The essence of learning how to be even a satisfactory anæsthetist is that the administrator shall feel personal responsibility in the case while *in statu pupillari*. In after practice the production of anæsthesia will be in most cases a necessary part of the day's work, and the hospital training should be adequate to prepare for this. There appears to be a growing fear of anæsthetics among our medical students, and some would have us believe that the dread of a *début* made in the coroner's court tends to aggravate this fear rather than to stimulate the student's enthusiasm for increased knowledge of the practice of anæsthesia. If this is so the dread engendered in the public mind by reading a garbled account of inquests offered for their perusal in the daily papers is reacting in a sinister manner upon medical training. If the present system is salutary, its drawbacks are probably remediable, and we may hope that the Departmental Committee's report may lead to this end. Hospitals are primarily for the amelioration of the sufferings of humanity, and their secondary use, the teaching of students, must take a subsidiary place. At the same time these uses coincide in some directions, and it remains for those who are responsible for the management of our great hospitals to evolve measures by which the one object may be achieved without undue interference with the other. The public is becoming more keenly alive to the importance of the subject of anæsthetics, though this may chiefly be shown by needless apprehensions, and we may anticipate that in future more thorough and systematic instruction will be given in our medical schools, and that there will be a more just appreciation of the value of efficiency in this department. Many hospitals have one or more residents whose duty it is to give anæsthetics in grave cases on occasions when the staff anæsthetists are not present, and were such posts established in all hospitals we believe fewer deaths would occur. The public mind would thus be reassured. When the production of anæsthesia is safeguarded by restrictive legislation, when the use of anæsthetising agents is taught systematically, and when all students are compelled to show practical and efficient knowledge of anæsthetisation before administering an anæsthetic on their own responsibility, many of the present dangers will disappear, and there is no doubt that the public will welcome such desirable changes.

Annotations.

"Ne quid nimis."

POOR-LAW BABIES.

AN interesting contribution to the literature dealing with the boarding out of pauper children is to be found in the *Nineteenth Century* for September in an article from the pen of Miss Janet Lane-Claypon, who gives an account of the system instituted in Berlin during the early years of the present century, and since brought to a high pitch of perfection, for boarding out infants thrown upon the hands of the public assistance authority of that city. We are all aware of the recommendations made by the Royal Commission on the Poor-laws for increased resort to boarding out, for its better supervision and organisation, and with the Minority's plan for dividing the responsibility for children above and below school age between the sanitary and educational authorities respectively. Public attention, however, with us has been directed recently more especially towards the care of the older children as distinguished from infants, although we have also seen discussed, not without some acerbity on both sides, the conclusions and criticisms of the Minority upon the high rate of mortality prevailing in workhouse nurseries. The early care of infants who commence their lives in the very unfavourable circumstances which bring them under the guardians' care presents undoubtedly many difficulties, the object proposed being the bringing up of the children so that they may reach maturity as sound-bodied men and women without imposing an unreasonable tax upon the ratepayers' pockets. Our friends in the capital of the German Empire belong to a practical and not an extravagant nation, to which they set an example of efficiency which is therefore worth considering. Their plan may be studied at length in the paper referred to, and it can be summarised as consisting in the *ne plus ultra* of medical care and nursing of the infant during a short period in a public institution or children's hospital, the Kinderasyl, followed by boarding out with foster-parents selected with scrupulous care, who rear it under the supervision of trained women inspectors and medical specialists. The infant has a clean bill of health before going to the foster-parents, and the supervision directed towards maintaining that condition achieves wonderful success. The Kinderasyl affords a centre of training for nurses and medical officers, which insures the efficiency of inspection in so marked a degree that it is found that the apparent advantages of boarding out children in the country do not

compensate for those due to the vigilance and advice of specially qualified officials not always obtainable away from the metropolis. Children falling ill when boarded out are brought back when desirable to the Kinderasyl or to the Waisenhaus, the latter being an institution which performs the same functions for children over one year of age as the Kinderasyl for those who are younger. If Miss Lane-Claypon is right in the opinion which she expresses that Hungary, Sweden, France, and Germany are all far ahead of us in dealing with Poor-law children, and even with those who are not Poor-law children, there is every reason why an attentive study of their methods should be made by all classes. We have said enough to show that the Berlin system contains much that should be of interest to medical men, and we commend it also to laymen interested in Poor-law work. We cannot, however, forget that the carrying out of any universal system of boarding out, accompanied by the necessary supervision and advice which alone can render its results satisfactory, must depend to a great extent upon the goodwill of that class in which the foster-parents must be found. We observe that groups of working men are being sent to Germany at the present time, apparently with a view to better qualifying them for the expression of opinions on the nation's fiscal policy. We hope that for other reasons also they may find social and economic conditions in Germany worthy of their attention. We do not suggest that they are experts in Poor-law administration or the management of infants, but their minds might be worth cultivating upon a subject directly affecting their own class. They might have something also to say as to the possibility of finding in London and in British centres of labour foster-parents of the class necessary. The well-organised social system of Germany and the characteristic submission of its people to discipline and official investigation, believed by many to be largely due to that country's military system and the training which this provides, probably render the provision of suitable homes for infants in need of them, as well as the carrying out of systematic inspection, easier operations than our own public assistance authorities would be likely to find them. In the United Kingdom experiments initiated in suitable districts and tactfully carried out might be followed by development and improvement, but we should be over-sanguine if we regarded success upon a large scale as a possibility of the near future.

QUACKERY: A PROPOSAL.

QUACKERY has been the bane, not only of the medical profession, but, which is of infinitely more importance, of the health and well-being of the people at large, probably ever since the dawn of medicine and certainly since historic times. Juvenal tells us how the fashionable Roman ladies sent for an Egyptian quack when they were ill, and to come down to later times the "Flos Medicinae," a Salernitan poem written, at any rate, before the fourteenth century, has the following complaint, which might have been penned to-day:—

> "Fingit se medicum quivis idiota, prophanus
> Judaeus, monachus, histrio, rasor, anus.
> Sicuti alchemista medicus fit aut saponista,
> Aut balneator falsarius aut oculista,
> Ilic dum lucra quaerit virtus in arte perit."

But quackery to-day has assumed a more rampant form than ever, and that principally owing to the spread of the ability to read and the existence of a press not over-careful what they put before the public either in their text or in their advertisements. Various remedies have been proposed from time to time, but nothing has as yet been done. We are led to these remarks by the receipt of a letter from Mr. H. Elliot-Blake urging upon us that it is not an anti-quackery society which is required so much as regulation and supervision of quackery. Mr. Elliot-Blake proposes that a public meeting should be called and a committee appointed to interview the Minister under whose department the matter would come. After this a Royal or Departmental Commission should be appointed. What Minister Mr. Elliot-Blake discreetly does not mention, while the fact that a Royal Commission has been promised escapes him. We see all the difficulties which he points out as sure to mark the foundation of an anti-quackery society, and we also consider that a public meeting might be of use if it were organised by some prominent citizens not belonging to the medical profession. But we have been recently told by a medical man, a Member of Parliament and warm supporter of the Government, that the medical profession is suspect in the House of Commons as being "out for fees," so that if any public meeting were organised under professional auspices the Government would look at it askance. Given the public meeting and its committee mainly of laymen, we would again suggest for consideration a remedy which we have upon many previous occasions put forward in these columns—namely, the licensing of all quacks of whatever shade. No one could say that this would be a legal recognition of quackery, for quackery is perfectly legal now. Neither could it be argued that the possession of a licence would imply a Government guarantee of the soundness of the treatment. Mr. Elliot-Blake, in referring to the press, says: "Another most important dependence of the quack-man and for the sale of his slop-medicaments rests on his free access to the paraphernalia of uncurbed advertising: that, to get any legitimate success, ought to be stopped." Mr. Elliot-Blake's strictures on the lay press would be more forcible if they had been made with discrimination and with recognition that certain editors and proprietors strive hard to grapple with the evil. However, we have pointed this out many times already. We believe that all movement for an inquiry into quackery and unqualified practice has reached an inchoate stage, and in the meantime if Mr. Elliot-Blake can organise his meeting nothing but good could come of it. For we are strongly of opinion that the more the public is made aware of the truth the less hold will gross quackery have upon them.

A NEW METHOD OF TESTING RENAL FUNCTION.

AMONG the numerous methods which have been introduced for the purpose of investigating the renal function and for comparing the efficiency of the two kidneys there are three which have become established as affording information of value in diagnosis. They are cryoscopy—i.e., the determination of the molecular concentration of the urine; the phloridzin test; and colour tests such as those with indigo-carmine and methylene blue. In an interesting paper recently contributed to the *Berliner Klinische Wochenschrift* Dr. Julius Wohlgemuth of Berlin describes a new method for which he claims certain advantages. The general principle of the three methods mentioned above is that the damaged kidney produces urine which is poorer in certain constituents, either normal or abnormal, than that excreted by the normal one. On the same principle it occurred to Dr. Wohlgemuth that ferments, such as the amylolytic or diastatic ferment normally present in urine, might show variations according to the functional activity of the kidneys. In support of this he found that when the kidneys were diseased the urine contained only traces of diastase. This was confirmed in animals by some observations carried out in cases of experimental nephritis at Dr. Wohlgemuth's suggestion by Dr. Goichi Hirata. The method originally adopted was to put into a series of ten test tubes small quantities of urine varying from 0·6

cubic centimetre in the first to 0·06 cubic centimetre in the last. The volume of fluid was then made up to about one cubic centimetre in each by means of physiological salt solution, and then 5 cubic centimetres of a 1 per cent. starch solution were added, prepared from Kahlbaum's "soluble starch." The test tubes were then kept in an incubator for 24 hours, when each was filled with tap-water up to a finger's breadth from the top. If the specimens from the two kidneys collected separately by catheterisation of the ureters were to be compared a similar set of tubes was prepared from both, and after incubation they were placed in proper order in series in the two stages of a special test-tube rack. To each tube one drop of a decinormal solution of iodine was added, and by this means the extent of the hydrolysis of the starch in each series was determined, and, as a result, the specimen containing the lesser quantity of diastase could be recognised, and this urine, therefore, was regarded as coming from the kidney whose functional efficiency was damaged. In order to avoid the 24 hours necessary for the completion of this test Dr. Wohlgemuth subsequently modified his technique so as to be able to carry it out effectively in half an hour. This modification consisted in using a solution of starch of 1 in 1000 strength instead of 1 per cent., and incubating in a water bath for half an hour at a temperature of from 38° to 40° C. The tubes were prepared as in the original method, but only 2 cubic centimetres of the weaker starch solution were added to each. After the half hour's incubation the tubes were cooled, their contents were diluted with tap water to within a finger's breadth of the top, and then tested with an iodine solution one fifth the strength of that used in the original method—i.e., a one-fiftieth normal instead of a decinormal solution. It was, however, usually necessary to add more than one drop of this solution. By the difference of the reaction in the two series the relative amounts of diastase excreted by the two kidneys can be estimated and their functional efficiency compared. Applying these methods to a considerable number of cases, both normal and pathological, and comparing the results with those obtained from the same urines by the cryoscopic, phloridizin, and indigo-carmine methods, Dr. Wohlgemuth obtained results so satisfactory that he regards this method of estimating the diastatic content of the urine as a valuable means of studying and comparing the efficiency of the two kidneys. He believes that it is at least as accurate as the cryoscopic method and superior to the other two. He also suggests that his observations tend to show that the method may be used, not only relatively, but also to determine the absolute efficiency of the kidneys, since he has found that under normal conditions the amount of diastase excreted varies within definite limits, and that in conditions of defective function the quantity falls below those limits. The special advantages claimed for this test are the short time necessary to carry it out—viz., only a little over half an hour—its simplicity, and the small amount of apparatus required, all that is necessary being test-tubes, a rack with two stages, two pipettes, a simple water bath, a thermometer, and the two reagents. Only a very small quantity of urine is necessary, as little as 2·5 cubic centimetres being sufficient, and it can be used for the cryoscopic method first if this is desired. Another important advantage is that no extraneous substance is introduced into the body as in the phloridzin and indigo-carmine tests, the latter sometimes causing pain on injection. The one disadvantage attaching to the diastase test is that the urine must be as far as possible free from blood; a few drops appear not to influence the reaction, but if much blood is present care must be taken in interpreting the results, especially if the urine containing the blood gives a higher value than the urine from the opposite kidney, which contains no blood, since in this case the kidney which has secreted the blood-stained urine is probably the defective one, in spite of the higher diastatic content of its urine. If, on the other hand, the blood-stained urine gives a lower diastatic value than that from the opposite kidney the result may be accepted as reliable. The determination of the relative functional efficiency of the two kidneys is often a matter of considerable moment in the diagnosis of renal disease, and especially in determining what treatment should be adopted. Dr. Wohlgemuth's method certainly appears to have some advantages, and if his conclusions are substantiated it promises to be a valuable addition to our means of diagnosis.

FLIES AS CARRIERS OF INFECTION.

AN American writer has said that flies originating in filth carry it wherever they go, and that going from their filthy breeding places to the habitations of man they carry to his food the germs of disease. This danger has been for some time past recognised in this country, though much vague assertion has been made regarding it. We therefore welcome the publication of investigations which have been conducted on strictly scientific principles. The publication to which we refer relates to a series of researches undertaken at the direction of the Local Government Board,[1] entitled "Further Reports on Flies as Carriers of Infection," being the third report issued upon the subject. In it Dr. G. S. Graham-Smith contributes an account of some extremely valuable and important observations on the ways in which artificially infected flies carry and distribute pathogenic and other bacteria. These researches throw much fresh light upon the question. Hitherto it was believed by many persons that the common means of conveyance of infection by flies was effected through the soiling of the animal's legs and feet, and that in crawling over food the fly left some of the material behind it upon the surface. But Dr. Graham-Smith's infection experiments show that non-spore-bearing bacteria do not usually survive more than a few hours on the fly's legs or wings. Nevertheless, such flies allowed to walk over sterile agar plates may cause infection for several days. This seems to be due to the fact that the flies frequently attempt to suck the surface of the plate, and in doing so infect it with the fluid regurgitated from the crop. When a fly tries to feed, for example, on sugar, dried milk or sputum, it first of all moistens the material with fluid from its proboscis and then sucks up the dissolved matter. Within the fly's crop non-spore-bearing bacteria often survive for several days, and they usually survive even longer in the intestines. The fæces deposited by such flies frequently contain the organisms in considerable numbers for two days and are generally infective for a much longer period. It is therefore not so much the crude material carried on the fly's feet that is the source of danger, but rather the infected "vomit" (the fluid regurgitated from the crop) and the fæces which contain the pathogenic organisms for some time after the fly has fed upon the specifically contaminated material. No evidence has been obtained that multiplication of the organisms takes place in the crop or intestine of the fly. Dr. Graham-Smith's infection experiments were made with a variety of pathogenic organisms, including B. typhosus, B. enteritidis, B. tuberculosis, B. diphtheriæ, B. anthracis, B. prodigiosus, and V. choleræ. He expresses the opinion that as his infection of the flies was produced in most cases by emulsions of pure cultures, it is improbable that under natural conditions flies would often have the opportunity of

[1] Local Government Board Reports on Public Health and Medical Subjects (New Series, No. 40), H.M. Stationery Office. Price 9d.

feeding on materials which contain pathogenic organisms practically in pure culture. It would, he adds, be premature to conclude that these experiments and observations described in the report do more than indicate that under exceptionally favourable conditions certain bacteria can be recovered from the contents of the alimentary canal and fæcal deposits of infected flies for some days after infection, and that these flies are capable for several days of infecting certain materials on which they may feed. The experiments with tubercular sputum and anthracic blood alone afford evidence as to the duration of life, in the contents of the alimentary canal, of pathogenic bacteria taken up under natural conditions. After quoting a number of instances recorded by other observers, at home and abroad, in which flies have been shown to have become grossly infected under natural conditions, it is pointed out that even these observations only prove that cultures of pathogenic organisms may occasionally be obtained from naturally infected flies; they do not afford conclusive evidence that such flies are a frequent source of disease in man by infecting his food. We are glad to learn that Dr. Graham-Smith hopes to continue these valuable investigations with naturally infected materials, not only with musca domestica, but with other non-biting flies. Appended to Dr. Graham-Smith's report is a summary of literature relating to the bionomics of the parasitic fungus of flies (Empusa muscæ) by Dr. J. M. Bernstein; and also a note by Dr. S. M. Copeman as to the work in hand, but not yet published, and as to proposed further work in reference to flies as carriers of infection.

THE CASE OF SURGEON-MAJOR FARMAR BRINGHURST.

WE have been favoured with a statement from Surgeon-Major Farmar Bringhurst, a retired member of the Army Medical Staff, who was recently indicted at the Guildford Assizes upon the grave charge of manslaughter based upon allegations of neglect upon his part, and arising out of the death of his wife at Egham. The grand jury, before whom the indictment was laid, declined to find a true bill upon the evidence adduced by the prosecution, and a verdict of "Not guilty" was formally returned by the direction of the Lord Chief Justice upon the coroner's inquisition, with the result that Surgeon-Major Farmar Bringhurst was discharged without having the opportunity to give evidence in his own behalf and to corroborate it by that of other medical men. This he was prepared to do, the gist of the testimony at his disposal being that the treatment which he applied upon his own responsibility, and particularly the use of morphia, were proper in view of the symptoms evinced by Mrs. Farmar Bringhurst. He was, moreover, desirous of establishing on oath the fact that it was through yielding to his wife's urgent wish that he abstained from obtaining the services of a trained nurse, undertaking himself the duties which would have been assigned to her and performing them devotedly to the end. The difficult circumstances in which the husband is placed in a case in which his wife is the patient, and in which alcoholism and the drug habit have induced her condition or contributed to render it almost hopeless, will be borne in mind. We have referred to the accused as not having had the opportunity of tendering evidence owing to the case not coming to trial because, although we are aware that, strictly speaking, he might have done so when before the magistrates, we realise how seldom counsel permits his client to go into the witness-box at this early stage of the proceedings, if committal is likely to take place in any event, and how impossible it is, owing to the expense, for a person of moderate means to call witnesses before the coroner, before the magistrates, and yet a third time at the assizes. It is to be observed, therefore, that although the "throwing out" of a bill of indictment by a grand jury is often treated as an emphatic declaration of a prisoner's innocence, and although it spares him the painful ordeal of trial by a petty jury, it may operate as a hardship. The accused person may welcome the grand jury's opinion that there is not a sufficient *primâ facie* case against him to justify his being put upon his trial, but at the same time may feel aggrieved that as the accusation has been publicly brought, has resulted in his being committed, and has been kept hanging over his head until the assizes, he has not been allowed to do his utmost to establish his complete innocence. Surgeon-Major Bringhurst is entitled to every sympathy in his regret that this opportunity should not have been afforded to him, and we are glad to record that he was willing and ready to make the fullest use of it.

THE TREATMENT OF FRACTURES OF THE BASE OF THE SKULL BY REPEATED LUMBAR PUNCTURE.

A FRACTURE of the base of the cranium is universally regarded as a very serious condition, one in which the prognosis must of necessity be guarded. According to Chudovszky the mortality in fractures of the cranial vault is 45·3 per cent. and in fractures of the base 64·2 per cent. More recent figures furnished by Maclaren are 20·2 per cent. for the former lesion, and 60 per cent. for the latter. It is true that within the last few years surgeons have advocated active interference in such cases to a greater extent: Cushing of Baltimore, for instance, recommends trephining subtemporally, and subarachnoid draining has also been employed. In the hands of skilful surgeons no doubt such procedures are justified, and in some published cases have been attended with remarkable success. Unfortunately, however, the condition of the patient is frequently so desperate that surgical measures only add to the shock from which he is suffering. A much more simple method, preferable to the pure passivity of medical treatment on the one hand and to the severity of surgical treatment on the other, consists in the reduction of the hæmorrhagic effusion by repeated lumbar puncture. Both in England and abroad cures by this means have been reported. Of course, in the case of cranial fractures the interpretation of statistics is a delicate manner, for among the "cures" it is difficult to exclude the possibility of spontaneous recovery whatever be the therapeutic measures adopted. It can scarcely be doubted, however, that the hæmorrhage accompanying the fracture, both from its volume and from the chemical phenomena associated with its absorption, constitutes the chief danger for the patient, and it is precisely this danger which is minimised by recourse to lumbar puncture. In *La Presse Médicale* for August 10th Dr. Apostolos G. Apostolides, physician to the Ottoman civil hospital in Smyrna, has published the details of two cases of fracture of the cranial base in each of which a complete cure was effected, the credit for which seems to be due to repeated lumbar puncture. The first of these concerned a young man, aged 22 years, who fell a distance of about 36 feet on to his head, and was picked up unconscious, bleeding freely though slowly from the nose, and presenting all the features of fracture of the base. His condition remained so grave that lumbar puncture was suggested more as a palliative than as a remedial measure. Forty cubic centimetres of cherry red sanguineous fluid were withdrawn under considerable pressure, the result being an immediate improvement in the patient's condition. During the next few days the procedure was repeated three times, the cerebro-spinal fluid being perfectly clear on the last occasion. The patient made an uninterrupted recovery. The other case was somewhat similar, and the success was equally striking. Whatever be

the verdict of the future, cases such as these are sufficiently encouraging to warrant recourse to lumbar puncture instead of the adoption of a waiting policy merely, thus allowing time for the development of infection of the meninges. Hæmorrhagic effusions are excellent media for bacterial germination.

FAMILIAL HYPERTROPHIC NEURITIS.

IN *La Semaine Médicale* Dr. Boveri of Pavia has described a comparatively rare disease to which the term "progressive hypertrophic interstitial neuritis" has been applied. In 1889 Gombault and Mallet published an account of a curious case, under the title "A Case of Tabes dating from Childhood," concerning a man aged 58 years who presented what were considered to be characteristic symptoms of tabes, but the anomalous feature was that the disease commenced almost in infancy and was associated with muscular wasting of the Aran-Duchenne type. In 1893 Déjerine and Sottas described the cases of a brother and sister who showed the classical symptoms of tabes in the shape of myosis, Argyll-Robertson pupil, ataxia, lightning pains, marked disturbance of sensibility, and loss of deep reflexes, to which, moreover, were added nystagmus, scoliosis, and gross amyotrophy. The result of a post-mortem examination in one of these cases was quite unexpected: the peripheral nerves were found to be greatly thickened, as were the spinal roots, especially those of the cauda equina. Evidently a new morbid entity had been discovered. Clinically, there appeared to be an amalgam of tabes and muscular atrophy, the underlying pathological stratum of which was hypertrophic interstitial neuritis. In 1908 Professor Pierre Marie described a family of six, no fewer than four of whom were afflicted with hypertrophic neuritis, but in a special form. The symptoms of tabes were not present to the same extent; the muscular atrophy was practically confined to the lower extremities; intentional tremor was noted, and a staccato articulation not unlike what is found in disseminated sclerosis. Otherwise, the clinical symptoms and signs were the same—scoliosis, wasting of the legs, with the "tabetic foot" well marked (a combination of pes equinovarus and pes cavus), absent deep reflexes, loss of sensibility, and in particular palpable enlargement of the superficial branches of peripheral nerves. That these cases may be more common than is usually supposed is to be inferred from the fact that Dr. Boveri mentions another which had been diagnosed as one of Friedreich's ataxia until the discovery that the peripheral nerves were greatly thickened revealed the true nature of the condition. From both the clinical and the pathological aspect the disease is remarkable. Hypertrophic neuritis is a definitely familial disease that may occur in either of two types (the Déjerine and the Marie variety). The features common to both are loss of deep reflexes, gross defect of sensibility, amyotrophy of the distal type, scoliosis, club-foot, and the underlying pathological condition. In the Déjerine type, however, further symptoms analogous to those of tabes are present—viz., lightning pains, myosis, Argyll-Robertson pupil, true ataxia, also nystagmus and fibrillary contractions. All these are absent in the Marie type, but there are found, on the other hand, intention tremor, dysarthria, and a muscular atrophy which is limited to the feet and legs, not generalised as in the first form. Pathologically the peripheral nerves are enormously thickened—in one case the sciatic nerve, 5 centimetres below its point of exit from the pelvis, was 19 millimetres in transverse diameter. The increase is due almost entirely to great overgrowth of the sheath of Schwann; there is less actual interstitial change, while the axis-cylinders themselves seem to be more slender than usual and the myelin sheath also is reduced. Degeneration in the posterior columns of the spinal cord, and to a less extent in the lateral columns, is described by Dr. Boveri.

PRECOCIOUS PARENTAGE.

OUR correspondent in China writes as follows: "The enclosed photograph is of a young couple whose precocious assumption of parentage has created some stir even among the Chinese. The characters round the photograph state that the mother is 8 years and the father 9 years old, but as a child is always reckoned in China as 1 year old at its birth this makes the parents each a year younger. Their names and village are given and the notice also states that in the first month of this year a child was born to them. In the photograph the mother can be seen suckling her child which measured one foot long at birth. The Governor

of Shansi, the province in which the birth took place, sent official particulars to Peking, but in order to make more sure I made further inquiries through a Chinese friend who lives in the neighbouring city of Tai-yuan-fu. He reports that the facts are as stated and that the boy is the father of the child, but I have been unable to obtain particulars of the development of his or her generative organs, whether the mother had previously menstruated, &c. In Taylor's 'Medical Jurisprudence' a case is mentioned of a mother 9 years old, but there is no record of so juvenile a father."

CHRONIC ECZEMA FOLLOWED BY FATAL GANGRENE.

IN the *British Journal of Dermatology* for July Dr. G. H. Lancashire has reported a very rare sequel of eczema—gangrene of the skin. A married woman, aged 54 years, was admitted into the Manchester and Salford Hospital for Skin Diseases in December, 1909, suffering from acute weeping eczema of the cruro-genital regions extending over the hypogastrium and inner and upper parts of the thighs. On the face and neck there was a subacute seborrhœic dermatitis. A chronic aural discharge was present. The patient was well nourished and did not appear to have lost strength. She had been treated for the eczema for over a year, during which there had been improvement and exacerbations. A few days after admission the eczema had disappeared from the upper part of the body, but in the cruro-genital region it remained obstinate. On Dec. 31st there

were nausea and vomiting and acute diarrhœa. The temperature was 99·4° F. The cruro-genital eczema was very acute; the surface was bathed in a sero-purulent discharge of offensive odour, which antiseptic dressings did little to mitigate. On the following day superficial ulcers of the size of a lentil appeared over the sacrum, and the evening temperature began to rise to 101° or 102°. On Jan. 4th, 1910, the whole of the raw surface on the abdomen and thighs was deep red and covered with punched-out ulcers of the size of a lentil. Each was filled with yellowish pus. After a day or two adjoining ulcers began to coalesce, forming little troughs. Later their bases dried up into blackish scabs, some of which towards the end were thrown off and replaced by granulation tissue. The general condition became grave; a typical septicæmic temperature developed, and the pulse became more and more rapid and feeble. The border of the diseased skin became sharply defined by a black ribbon-like scab of dry gangrene, outside of which the skin was congested. Scattered ulcers appeared on the healthy skin adjoining the diseased area and rapidly became gangrenous and scabbed. The temperature became subnormal and the patient died comatose on the 14th. Treatment consisted in trying by soothing antiseptic lotions (compound lead lotion, with cresol and carbolised linimentum calcis) to control the inflammation and to diminish the sepsis. Dressings were constantly applied. Microscopic examination by Dr. Arthur Sellers showed extensive gangrene of skin, involving in many places the whole thickness and extending for a few millimetres into the subcutaneous tissue. Cocci and bacilli were present in enormous numbers. The staphylococcus pyogenes aureus and the bacillus pyocyaneus were cultivated from the skin, spleen, liver, and kidney. Death was apparently due to septicæmia from the mixed infection. It was thought that the bacillus pyocyaneus was the chief organism, and that the otitis was a possible source of infection. In many respects the clinical features corresponded to those described by the late Dr. Radcliffe Crocker in "dermatitis gangrænosa infantum," in which several investigators consider the bacillus pyocyaneus the infecting germ.

THE PHYSIQUE OF THE PHTHISICAL.

UNDER the above heading we publish this week a contribution by Mr. H. de C. Woodcock, honorary physician to the Tuberculosis Hospital, Leeds. He draws attention to certain points in the physique of patients suffering from pulmonary tuberculosis, some of which have not received much attention in text-books dealing with this disease. He appends tables giving the results of a large number of cases which he has investigated. Although his results and conclusions are interesting, similar observations from other physicians will be necessary before they can be accepted as of actual practical utility. Mr. Woodcock lays stress on the peculiar appearance of the soft palate which is common in marked cases of pulmonary tuberculosis. The palate is of a "pearly bluish-white tint, and is covered with a somewhat mucoid moisture." He regards it of some value in prognosis, considering it of sinister import. We should hesitate to confirm this opinion, and should be inclined to place it in the same category as the red line on the gums, which was at one time much commented upon by writers on pulmonary tuberculosis, but which has been shown to occur in other cachectic states. The "hand ratio" to which he refers is a matter which would require much trouble to work out, and its actual value in practical work is a matter of doubt. The hyperextension of the fingers on the metacarpals or of the terminal on the penultimate phalanx is not only a sign found in the case of patients in an advanced stage of pulmonary tuberculosis, but is also seen in other chronic affections, especially when emaciation is marked. Clubbing of the fingers is frequently found in tuberculous subjects, and has, as Mr. Woodcock remarks, lost some of the value formerly attached to it. The remarks on the occurrence of pulmonary tuberculosis in soldiers, sailors, and others "who might be classed under the general name of 'wanderers,'" are interesting. The incidence of the disease in individuals of the class to which he refers is gradually attracting attention. In the case of sailors, the confined spaces in which they sleep and feed are doubtless unhealthy and counteract the beneficial effects of the sea air and sunshine to which they are submitted. Some of the signs inquired into by Mr. Woodcock are certainly worthy of further investigation.

THE AFTER-EFFECTS OF HEAD INJURIES.

IT is not sufficiently recognised that apparently slight injuries of the head from which recovery soon takes place may later be followed by grave and permanent mental impairment. In the *Polyclinic* for June Mr. C. T. Dent has published an important article on the After-effects of Head Injuries. As chief surgeon of the Metropolitan Police he has unusual opportunities for following the after-history of a considerable number of cases of head injury. He finds that mental disorder so grave as to require certification (traumatic insanity) is not a common sequel, but mental impairment sufficient to diminish the patient's capacity for work is not uncommon. He particularly calls attention to one factor in determining the incidence, severity, and persistence of the results to which sufficient attention has not been paid—responsibility. The moment a person is beset by the consciousness of responsibility in his work his capacity is lowered. This is well shown in policemen to whose work in proportion to their position and education a heavy responsibility attaches. The following are some typical examples of the serious after-effects of apparently slight head injuries to them. A strong healthy constable, who was on duty, was picked up semi-conscious on the roadway. He recovered after 10 minutes and stated that he had jumped off a tramcar in motion. There was no doubt that the accident had happened and that he had struck his head in falling. The injury appeared trivial and he seemed to recover so completely that he returned to duty in five days. Three days later his turn for leave came and he went to the country. While there he behaved so strangely that a medical man was summoned and he was sent back to London. He had no recollection whatever of going to the country or of what took place while he was there. There was no suspicion of alcoholism. He wrote several incoherent letters characterised by marked iteration. In a few days he seemed to have recovered. He was invalided from the force, but later he was apparently well and desirous of rejoining. In another case a constable of 17 years' service, who had been injured on duty on nine occasions, was kicked on the side of the head and neck and soon became partly unconscious. He improved and returned to duty in three months, but in a few days he broke down again. He progressively deteriorated, and about a year after the injury there was decided melancholia. Six months later the melancholia was less, but he was very irritable and inclined to be suicidal, and was rapidly drifting towards insanity. In a third case a constable in a struggle with a drunken prisoner was thrown and fell heavily on the back of his head. He was picked up unconscious, but after 20 minutes he partly recovered consciousness. He soon recovered from his injuries and after 13 days resumed

duty. A year later he had delusions in reference to a murder that had taken place, and persuaded another constable to arrest a man who was entirely innocent. After a few days he recovered from this attack and had no recollection of the episode. Two other cases are related. In all the cases malingering could be excluded; the men had everything to gain by continuing the work to which they had returned. The cases had the following features in common: 1. The head injury never appeared grave. 2. Recovery rapidly took place. 3. After intervals varying from five days to ten years the men resumed duty. 4. All showed subsequently mental impairment of a similar nature. 5. In none was it sufficiently grave to be certified as insanity. 6. All began to improve again as soon as they ceased work for the second time, but not so rapidly or so thoroughly as before. 7. The mental symptoms developed after an interval following recovery from the accident, and their onset was precipitated by the resumption of anxious and responsible duties. The factor of responsibility largely determines not only insanity, when it occurs, but also any milder mental effects. In these cases the sense of responsibility which formerly sat lightly on the men's minds seemed to weigh them down with constantly increasing heaviness. If the sense of responsibility attaching to the occupation is slight, recovery may be favoured by gradual resumption of work.

THE BONE CALLED "LUZ."

THE most careful searching in the last published and amplest treatise on osteology will not result in the discovery of the bone called "Luz." It will be necessary to go to the Frankfort edition of the "Theatrum Anatomicum" of Caspar Bauhinus (1621) for a description. "It is stated by Hebrew writers to be a bone which cannot be destroyed by fire, water, or any other element, nor be broken or bruised by any force. Its site is in the spine from the eighteenth vertebra to the femur. We read that the Emperor Hadrian once asked Rabbi Joshua, the son of Channi, how God would resurrect man in the world to come. He made answer: 'From the bone Luz in the spinal column.' When Hadrian asked him how he came by this knowledge and how he could prove it, the Rabbi Joshua produced the bone so that the Emperor could see it. When placed in water it could not be softened; it was not destroyed by fire, nor could it be ground by any weight; when placed on an anvil and struck with a hammer the anvil was broken in sunder, but the bone remained intact." Hieronymus Magius represents that, according to the Talmudists, the real bone is near the base of the skull, whether it be in the base itself or in the spine. Vesalius writes that this ossicle is called *Albadaran* by the Arabs, resembling a chick-pea in size and shape, and Cornelius Agrippa describes it as *magnitudine ciceris mundati* (the size of a shelled pea). Different anatomists have held it variously to be the sacrum, the coccyx, the twelfth dorsal vertebra, one of the Wormian bones in the skull, and one of the sesamoids of the great toe. To have confounded it with the sacrum is natural enough on account of the name given to this bone by the ancients *ἱερὸν ὀστέον*, about which, however, there has been much controversy, and the coccyx is that bone called *al ajb* by the Arabs, which Mohammed stated to be incorruptible and to serve as a basis for the future edifice at the resurrection. The twelfth dorsa vertebra, as the turning point and centre of the spine, the Wormian bones on account of the mystic properties which were ascribed to them, and the sesamoid bones of the great toe on account of their shape and hardness, have all claims to be regarded as the "Luz."

THE SYMPTOMS OF RUPTURED ABDOMINAL HYDATID.

WE publish in this week's issue of THE LANCET an interesting note by Dr. J. E. Barling and Professor D. A. Welsh of Sydney describing a group of symptoms occurring with some frequency according to their experience in hydatid disease complicated by rupture or leakage into the peritoneal cavity. The symptoms referred to are eosinophilia, peritonitis with effusion, and urticaria. Their observations were made on six cases, five being hydatid of the liver and one of the spleen. Eosinophilia is well known to occur as a reaction to many forms of metazoan parasites, and has frequently been described in hydatid disease. Dr. Barling and Professor Welsh have found that in uncomplicated hydatid disease in man it is by no means invariably present, as many as 25 per cent. showing no eosinophilia, or only a very slight degree. When rupture into the peritoneum occurs, however, they find that it is very marked. In one of their cases the eosinophiles constituted 54 per cent. of the leucocyte count. The second sign of rupture they describe is the marked peritoneal effusion which results even when only a small escape of the hydatid fluid occurs. The irritation set up appears to be very marked and considerable effusion develops as a result. The urticaria resulting from rupture of a hydatid cyst has long been known, and is well recognised as a sign of rupture or escape of fluid. This sign occurred in four out of the six cases observed by Dr. Barling and Professor Welsh. This symptom complex is of considerable clinical interest and diagnostic value, and in any case where hydatid disease is suspected the occurrence of eosinophilia in association with a peritoneal effusion may afford valuable assistance towards arriving at a diagnosis. It is also of pathological interest to notice that the results of rupture into the peritoneum appear to produce a local inflammatory reaction, a more marked leucocytic reaction, and in some cases a general toxic action as shown by the urticarial rash. Some years ago Brieger separated a toxic substance from hydatid fluid to which possibly the urticaria at least may be attributable. According to Viron this substance is allied to the toxalbumins.

Mr. Peyton T. B. Beale, senior surgeon to the Great Northern Central Hospital, surgeon to King's College Hospital, and for the last three years Dean of the Medical School, has resigned all his London appointments and entered practice at Hythe. For family reasons it had become necessary that Mr. Beale should live in more favourable climatic conditions than London can supply, and his numerous friends will join us in wishing him well in his new career.

AMONG the recent appointments which Queen Alexandra has made in her Household are the following: Sir Francis Henry Laking, Bart., G.C.V.O., K.C.B., Physician-in-Ordinary and Surgeon Apothecary to the Household; Sir Frederick Treves, Bart., G.C.V.O., C.B., Surgeon-in-Ordinary; Sir Alan Reeve Manby, M.V.O., Physician Extra-Ordinary and Surgeon Apothecary at Sandringham; and Mr. Milsom Rees, Laryngologist.

THE next meeting of the North-East London Clinical Society will be held at the Prince of Wales's Hospital, Tottenham, on Thursday, Oct. 13th, at 4.15 P.M., when the opening address of the session will be given by Dr. Frederick Taylor on the Diagnosis of Prolonged Pyrexia.

THE opening lecture of the winter session of the West London Post-graduate College will be delivered by Dr.

Donald Hood, C.V.O., on Monday, Oct. 10th, at 5 P.M., his subject being "Specialism in Medicine."

Field-Marshal Viscount Kitchener of Khartoum will distribute the prizes at the opening of the seventy-sixth winter session of the Middlesex Hospital Medical School on Monday next, Oct. 3rd, at 3 P.M.

THE introductory lecture at the Royal Veterinary College will be delivered on Monday afternoon, Oct. 3rd, at 3 P.M., by Professor H. W. Marett Tims.

THE OWNERSHIP OF MEDICAL PRESCRIPTIONS.

BY H. WIPPELL GADD,
OF THE MIDDLE TEMPLE, BARRISTER-AT-LAW.

A MEDICAL prescription may be defined as the written opinion of a physician, which specifies the particular remedies which are required by the patient who consults him. It is written as the result of a diagnosis of the patient's condition, and its purpose is limited in time as well as in person. It is usually written in Latin and expressed in technical terms, so that it does not necessarily convey any information to the patient, but is rather a recipe which he can take to any compounder of medicine, to whom he chooses to entrust it, for conversion into concrete form. In the best interests of the patient, the use of the prescription should be limited, as the very efficiency which it may possess in the morbid condition of the person for whom it was written may render it noxious or even toxic to the same person when in a state of health, and still more so to other persons of different age, sex, or habits of life. Such considerations which are patent to the physician who writes the prescription are not always fully appreciated by the relatively ignorant person for whom it is written; and the former may well desire to know the measure of control, if any, which he can retain over the document after it has left his hands.

The relation between physician and patient is one of contract, expressed or implied, the consideration being the fee paid, and it would seem that, in the absence of conditions to the contrary, on completion of the contract the prescription becomes the absolute property of the person who has paid the fee. In other relations, when the expert opinion of a professional man is given for the consideration of a fee, the property in any documents prepared in accordance with, or as an expression of, such opinion, vests in the person who has paid the consideration.

Thus, a client for whom a solicitor prepares certain documents is entitled to the ownership, not only of such documents, but also of all drafts and papers connected therewith (*vide Ex parte* Horsfall (1) 1827, 7 B. & C. 528).

The property is not always, however, absolutely unqualified. Thus, an architect retains the copyright, as drawings, in plans which he may have prepared to the order of a capitalist, although the ownership of the plans vests in him who has paid for them (comp. Gibbon v. Pease, 1905, 1 K. B. 810).

Sometimes the reverse holds good, the copyright vesting in the one who pays, and the ownership in him who works. Thus, a photographer has property in the negative which he has prepared in order to print portraits of a sitter, but the copyright in such portraits vests in the sitter, and the owner of the negative may not produce copies for sale or exhibition without his consent (*vide* Pollard Photographic Co., 1888, 40 Ch.D. 345).

Again, it is the practice of analytical chemists when handing reports of investigations, made for clients in return for a fee, to such clients to make it a condition that the report or certificate shall not be published or advertised without the consent of the analyst. This custom was upheld in an unreported case (Clark *v.* Dibdin and Thudicum), which was heard at the Westminster county court on May 1st, 1901. Here an engineer brought an action against a firm of analysts and claimed damages "for deteriorating the value of a written report by writing upon it." The defendants had reported on a gas burner and the report was subsequently returned to them for alteration. The defendants returned the report to the plaintiff with the words "not for publication" written across the face of it. The plaintiff contended that this made the report valueless to him, and stated that he considered he possessed a right to use the report in any way he thought fit. For the defendants it was contended that such reports were made entirely for the information of the person applying for them, and not for the purpose of publication or advertisement. Further, that they had a right and power to prevent any infringement of their right in any printed or written unpublished document. Evidence was called to show that it was the universal and recognised practice of the profession of analytical and consulting chemistry to treat such reports as not for publication or advertisement without a special agreement to that effect. The judge (Lumley Smith, K.C.) held that the defendants had established their contention that such a report was not for publication in the general sense, and that the plaintiff could not make use of it in the way he intended. The defendants had, however, exceeded their rights by writing across the report after the first delivery, when it became the property of the plaintiff. They would have been justified in returning it with a letter stating that the report was not for publication or in having written the words across the report before it was originally issued. They had technically exceeded their rights, but there was no damage. For the technical trespass the judge awarded contemptuous damages.

But in the case of prescriptions, the danger is not that of publication. Publication, in the technical sense, there must necessarily be in the handing of the prescription to a pharmacist for compounding. Moreover, if the prescription specifies a scheduled poison, the pharmacist is under a legal obligation to make a copy of it in a book kept for that purpose (*vide* 31 & 32 Vict. Cap. 121, Sec. XVII.). But to publish, in the general meaning of the word, a prescription as the writer's specific for a particular disease, or to put upon the market a preparation compounded in accordance with its directions, with the name of the author attached, would so damage the prescriber's professional standing and reputation that he would doubtless be able to obtain an injunction restraining the owner of the prescription from so using it. The difficulty lies rather in preventing the prescription being dispensed too frequently, either for the person for whom it was originally written, or for anyone else who may obtain possession of it. Conditions might, of course, be made by the physician with his patient at the time of consultation, specifying the maximum number of times the prescription should be compounded, or the date after which it should cease to be used, and such conditions might be endorsed upon the face of the prescription, but it is difficult to see how they could be enforced as between physician and patient.

The most feasible solution of the problem would appear to be the treatment of the question as one of etiquette between physician and pharmacist. Pharmacists are accustomed, and are indeed called upon, to exercise discretion as to whom they shall sell potent drugs, and would respect and faithfully observe any directions which might be addressed to them on the face of a prescription. If in rare instances such directions were habitually ignored by any unscrupulous practitioner, recourse should be had not to process of law but to the disciplinary powers possessed by the Pharmaceutical Society of removing from its membership any member who has been guilty of any act or conduct which is contrary to, or subversive of, the interests of the Society.

BODY METABOLISM IN CANCER.[1]

CONSIDERATION of the curves of cancer mortality in the human subject, whether male or female, discloses the interesting and important fact that cancer is not, as is usually thought to be the case, a disease of old age, however much it may be related to senescence of certain of the body tissues As a matter of fact, the disease is of extreme rarity in the later years of life, especially in the female sex. Thus the characteristic feature of the age incidence of cancer, as pointed out by Roger Williams and others, and as demonstrated by the returns of the Registrar-General, is not its continued increase with advance of years, but rather its

[1] Report of a committee of the British Association, consisting of Professor C. S. Sherrington (chairman) and Dr. S. M. Copeman (secretary).

disproportionate augmentation in the post-meridian periods of life—i.e., between the ages of 45 and 65 years—liability to the malady waxing as the reproductive activities wane. The facts, indeed, clearly show that cancer is *not* a disease of senility merely, which *per se* plays no part in its development.

In the animal world the age incidence of cancer is evidently governed by a similar law, as has been demonstrated by Stricker for horses and dogs, and by Bashford and Murray for mice, all these observers being in agreement as to the rarity of malignant tumours in early life and their relative frequency in later life, antecedent, however, to onset of old age.

In the light of these facts it would seem not improbable that the onset of malignant disease, whether in man or the lower animals, may have intimate relationship with diminished or perverted functioning of the reproductive organs, which, under normal circumstances, may be regarded as exerting—possibly by virtue of their so-called "internal secretions"—some restraining and coördinating influence on the growth of the somatic tissue elements.

Evidence of the existence of such a controlling influence is found in the fact, on which there is now general agreement among those engaged in the experimental investigation of cancer, that whereas transplantation of "spontaneous" cancer in the mouse to normal individuals is apt to prove successful in but few instances when full-grown animals are employed for experimental purposes, complete insertion success has not infrequently proved possible of accomplishment when mice of not more than six or seven weeks old are used. In view of the further fact that fanciers are agreed that the mouse is incapable of reproduction before the age of three months, while six months is generally stated to be the earliest age at which these animals should be mated in order to ensure healthy offspring, it would appear that the greatest measure of success in experimental transplantation of cancer in this animal is obtainable only during the period of life antecedent to full or even commencing activity of the reproductive functions. On the other hand, implantation of cancer material from one mouse to another is *least* likely to be attended by success when the recipient is of an age at which these functions have attained the stage of full activity.

For these and other reasons it appeared desirable to investigate the question as to whether any of the products of the reproductive glands—presumably given off, under normal circumstances, in the form of an internal secretion—can be shown experimentally to influence, in one or another direction, the development of cancer as witnessed when this disease is experimentally produced in the mouse. For the prosecution of this investigation facilities have been most kindly afforded by the Executive Committee and the Director (Dr. Bashford) of the Imperial Cancer Research Fund.

Although at the present time but little doubt exists as to the production of an internal secretion by the testes and ovaries, practically nothing is known of its nature and composition. It has, however, been suggested that its main constituent is in all probability derived from metabolism of nucleo-proteids which are present to so considerable an extent in the tissues of the reproductive glands. Professor von Poehl, of St. Petersburg, and others have, indeed, claimed that spermin, a crystallisable substance which has been isolated from the testes, prostate, ovaries, and in less amount from certain other organs and tissues, constitutes the essential principle in question. For the purposes of the present investigation, therefore, it appeared desirable, in the first instance, to make use of this substance (of which Dr. von Poehl, the successor of the late Professor von Poehl, kindly provided supplies), employing, in addition, freshly prepared emulsions of mouse testes, extracts of dried and powdered testes freed from nucleo-proteid, boiled watery extracts of the testicle of various animals, and a solution of nucleinic acid of orchitic origin. In every instance the action of all these various substances was tested on the mouse by hypodermic injection, while fresh emulsion of testes and solutions of nucleinic acid were also administered internally by a method of experimental feeding devised for the purpose.

For each series of experiments a number of mice were employed which had been inoculated with cancer material, by a member of the staff of the Imperial Cancer Research Laboratories, from ten days to three weeks previously, by which time most of the animals had developed tumours, sometimes of considerable size, at the site of operation. The precise area of the resulting tumours in each animal is recorded on charts by one of the laboratory attendants 10 days after implantation, and subsequently at weekly intervals. In every experiment one lot of inoculated mice was set aside as a control. Each series of experiments has extended over a period of five or six weeks, or occasionally even more, so that the work has necessarily taken up a considerable period of time. Owing also to the exigencies of the special work of the laboratory staff, and of official duties on the part of the member of this committee to whom the investigation was entrusted, delay in the prosecution of the work has from time to time proved unavoidable.

As the work is still in progress it would serve no useful purpose, on the present occasion, to enter into details of the numerous experiments performed. It is therefore proposed only here to set out a brief statement of the main results which thus far have been obtained.

As a preliminary step a number of mice were injected hypodermically with a 2 per cent. solution of spermin in normal saline solution, in quantities varying from 0·1 to 0·4 c.c., in order to make certain that the employment of this substance was not productive of any ill effect on the mouse. This having proved to be the case with these doses, 4 mice which had been inoculated just previously with 0·05 gramme of tumour 63/41A in the left axilla, were subsequently injected daily, with the exception of Sundays, for a period of 17 days, with 0·4 c.c. of the spermin solution. By this date three out of the four tumours which had arisen in these mice, as the result of inoculation, had entirely disappeared, while of eight tumours which had arisen in 10 control mice, inoculated on the same date, *none* had disappeared, although two had somewhat decreased in size.

On Feb. 4th of the present year 20 mice were inoculated with a very rapidly growing strain of tumour, of which 10 were kept as controls in a separate cage. A week later tumours had appeared in all these mice. From this date, for a period of nearly three weeks, 10 of the mice were injected daily, except on Saturdays and Sundays, with 0·4 c.c. of the spermin solution. As by this time the result obtained with the injected as compared with the control mice merely showed differences which might be considered as coming within the limit of experimental variation, the work was not continued.

In view of the apparent difference of result obtained in these two experiments, Dr. Bashford suggested that for future work it would be desirable to employ for purposes of inoculation a slow but continuously growing tumour (Twort 30B.), which, in this respect, most nearly reproduces the characteristics of a spontaneously occurring tumour. With this material Dr. Murray inoculated 40 mice on March 4th, of which 10 were kept as controls, the other 30 being divided into three lots of 10 each, and kept in separate cages. These were respectively injected daily—(*a*) with fresh emulsion of mouse testis 0·4 c.c. each; (*b*) with spermin solution; and (*c*) Poehl's orchidin solution in similar quantities. On March 21st eight tumours had developed in each lot of 10 mice, while one of the controls had died. By April 4th, of the spermin series, five of the tumours had disappeared; of the testicle emulsion series all eight tumours showed a definite increase in size; while of the orchidin series the tumours exhibited no appreciable difference from those of the controls. At this point the experiment was unavoidably interrupted.

In a further experiment on somewhat similar lines half the number of the experimental mice, in addition to being injected daily with spermin, had fresh testicle emulsion administered by the mouth. These latter, at the end of four days, showed a considerable diminution in size as compared with those injected with spermin only, one tumour of fair size having even at so early a stage of the experiment disappeared completely. Subsequently, however, possibly for the reason that the dose of spermin, which was larger than in previous experiments, was repeated too frequently, all the remaining tumours exhibited slow but steady increase in size up to the period when, three weeks later, the experiment was terminated.

In other experiments a testicle extract was employed which had been freed from nucleo-proteid, and which therefore contained, in addition to spermin, creatin and other extractives as well as inorganic salts. The use of this material for the purposes of injection in a large number of mice eventually afforded no appreciable difference from the control mice as regards the size of the tumours, the result thus differing on the one hand from the definite increase obtained with the use

of *fresh* testicle emulsion, and on the other from the diminution obtained in certain instances in which a solution of spermin was employed.

Certain of these experiments are now in process of being repeated with large numbers of mice, by independent workers in the laboratories of the Imperial Cancer Research Fund, where also, thanks to the kindness of Dr. Bashford, a further series of experiments are also being carried out, in which nucleinic acid of orchitic origin is to be employed, both hypodermically and by oral administration—in the latter case both with and without the simultaneous use of hypodermic injections of spermin.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

Security Bolts or Not?

THERE is no doubt that security bolts have given trouble: firstly, unless care is taken the inner tube may be nipped by them, but chiefly, even if they be adjusted correctly, dust and wet may enter. Is it possible to dispense with security bolts? From a theoretical point of view, if the air pressure is sufficient and there is an exact fit between the beads of the cover and the rim clinches they should be needless. However, as the pressure in the inner tube may become insufficient, and driving strains, skidding, and the sudden application of the brakes may tend to make the cover creep, there is no doubt that something extra to hold the cover to the rim is essential. Still it does not follow that a number of security bolts must be used. In fact, all that is required can be obtained by one security bolt, or, what is better, the valve and one security bolt can be combined, as is the case with the Michelin bolt valve, or the Hobson tyre clamp may be used. In the Michelin device a boat-shaped plate is held in position on the body of the valve, and when the latter is in place, and the valve hood which replaces the ordinary inner tube valve cover is screwed down, the edges of the plate press firmly against the beads of the cover and lock them into the rim clinches, and thus all ordinary security bolts can be dispensed with. If it is decided to do away with the security bolts, the bolt holes in the rim must be stopped up. Ordinary small flat-headed bolts that can be obtained from any ironmonger may be used, or wood plugs driven tightly in can be employed, providing that they do not project on the inside of the rim. Messrs. Michelin advocate special dummy bolts which they supply for the purpose.

Dual or Single Ignition?

As a rule most foreign car manufacturers content themselves with fitting a single method of exploding the mixture, and this is now invariably the high-tension magneto. I have had a good many letters from medical motorists on this matter as to whether it is safe to rely upon the magneto alone. There is no doubt that the magneto has of late years been greatly improved; still, slight defects may arise. Though the majority of these defects can, if magneto spares are carried, be remedied on the road, yet if a "short" should develop in the armature winding, then, unless a second ignition is fitted, the motorist is stranded. For the profession, therefore, it seems desirable that a second ignition should be fitted, and if this is provided the two systems should be absolutely independent of one another.

The Care of the Magneto.

An important preventive of trouble is to insist that the magneto is positively driven—that is, by a dog clutch, and anyway not by a chain. Though a broken chain can be easily repaired it is not easy to replace the chain so that the timing is correct. Also, if the chain wears the timing of the spark will be erratic, sometimes ahead and at others behind the correct position. The commonest cause of trouble is, however, too great energy with the oil-can. Because a couple of oil holes are provided it does not follow that they should be dosed with lubricant whenever a halt is made. With other parts too much oil is better than too little, but in this instance the converse holds; a few drops of oil twice a month are ample. Swamping with oil may lead to the destruction of the wiring insulation and internal "shorts." It may also have a bad effect on the fibre rollers which actuate the make and break. The commutator and its brushes, too, must be maintained electrically clean—that is, free from any deposit of oil or carbon that may have collected between the brass plots. The platinum points of the make and break must be kept clean. It is rarely necessary to dismount these parts for adjustment, but should they become pitted after long use, they may be made true with some fine emery cloth, or carefully smoothened with a file. The magneto is really a simple piece of mechanism. A short time spent under the direction of someone who understands it will result in a familiarity with its adjustment that may obviate many lengthy delays and much irritation.

The Appearance of the Motor-body.

I recently spent a short time at a coachbuilder's and the manager explained to me that a slow drying varnish should be used and that it should be allowed full time to dry in the paint-shop before exposure to wear. Often, though the varnish may appear dry, and though it may not stick to the fingers, it is but the outside that is dry and the underneath portion is soft, and if the car is taken out in that condition its brilliant appearance will be of short duration. The impatient purchaser harasses the motor-dealer and the latter in his turn worries the coachbuilder. Neither desires the order to be cancelled, so some expedient is resorted to, such as washing the car with cold water. This hardens the outside of the varnish, but unfortunately does not affect the interior surface, and the earlier delivery of the car thus obtained may ensure the short life of the paint-work. The great advantage of the ex-coachman chauffeur is that he certainly does know how to look after the body-work of his car. I am afraid this cannot be said of all chauffeur mechanics. The main secret of the durability of the paint-work depends on the washing. Plenty of water laid on with a hose should be used so as to soften and carry away all the mud. Then the body should be wiped dry with a chamois leather or some stockinette material, and finally polished by an up-and-down movement with a chamois leather which should be kept exclusively for that purpose. The addition of petrol or paraffin to the washing water will assist in the cleaning, but will also help in removing the varnish, and should therefore not be allowed. Touching-up the body and revarnishing once a year maintain a good appearance and postpone the day when repainting must be done; also the woodwork is thus preserved.

LONDON HOSPITAL EXPENDITURE IN 1909.

THE seventh annual report of King Edward's Hospital Fund for London has recently been published. It will be remembered that when the late King Edward graciously consented to become patron of this Fund, which will always be intimately associated with his name, he made it a condition of future participation in its benefits that each hospital should furnish the Fund with uniform particulars of annual expenditure.

The preparation of annual reports for this Fund was begun in 1903 by Mr. Danvers Power, whose investigations at that time did not extend to more than 16 of the London hospitals. But the earlier reports contained confidential matter, and their circulation was accordingly restricted to the contributing authorities.

The first report printed for general circulation was that for 1908, in which the principles and objects of these documents were fully set forth. But it was not until the following year—namely, that to which the present report relates—that the difficulty of instituting valid comparison between the several hospitals was completely surmounted, and this was accomplished by the adoption of a uniform system of hospital account-keeping prepared for the Fund by Mr. John J. Griffiths, F.C.A., and adopted with the concurrence of a committee of hospital secretaries.

Sir Savile Crossley and Mr. Frederick Fry, the honorary secretaries of King Edward's Hospital Fund, have rendered a public service by publishing the present detailed reports on the expenditure of the great majority of the London hospitals which received grants from the Fund in the year 1909. The statistical part of the report has been compiled for the Fund by Mr. R. H. Maynard, who has marshalled his facts with

great care and with considerable actuarial ability. The report deals with 17 of the larger and 15 of the smaller general hospitals, each of the former containing more and each of the latter fewer than 100 beds, in daily occupation. In addition to these account is rendered of four hospitals for consumption, five for the diseases of women, seven for those of children, five for ophthalmic cases, three for epilepsy, and 43 for other diseases. The tables in the present report afford, for the first time since the introduction of the uniform system of account-keeping, opportunity of making comparison between one year and another with respect to hospital expenditure. In drawing conclusions from the tables in the report it must be remembered that they only provide material for comparison of outlay and take no account of the relative value resulting from that outlay, except in so far as this is expressed in terms of average length of stay in hospital per in-patient or of average number of attendances per out-patient. It goes almost without saying that even if the degree of economy in management were the same at all the hospitals there would still remain considerable differences of cost, dependent on the kinds of cases admitted and on the methods of treatment. Obviously, the main question in each case is, in the words of the report, to determine "how far a given cost *above the average* is justifiable or whether a given cost *below the average* is attained at a sacrifice of full efficiency." In all the tables it is the average that is taken as the basis of comparison, and there is no suggestion that the lowest is put forward as a model for imitation. In the year 1905 the reduction in expenditure in the case of the 16 hospitals was valued at £24,000 per annum, and in 1906, in the case of 48 hospitals, at an additional £18,000 per annum. Without in any way suggesting that the ideal of economy had been reached, it would be unreasonable to expect the same rate of decrease in cost to be continued indefinitely. Mr. Maynard, however, reasonably contends that unless the cost again increases the saving may be regarded as an annual one. "It would appear," he tells us, taking everything into consideration, "that the net figure of about £6000 fairly represents a real progress in the direction of increased economy during the year 1909, and, in so far as the circulation of these reports has assisted towards that end, the result may be some reward to the hospital officials for the labour involved in preparing the printed and written material required by the Fund for the purpose."

In glancing rapidly at the items of expenditure in the summary table it is disappointing to note the retention of the heading "rates and taxes." Having regard to the absolute necessity of gratuitous hospital provision for the class of the community immediately above paupers, it is surely time that, as regards Government taxes at any rate, this heavy deduction from the contributions of the charitable should cease. There is a justifiable precedent for such relief in the case of life-insurance premiums. This is a question which we submit not for the first time for the earnest consideration of Parliament.

SIXTY-FOURTH REPORT OF THE COMMISSIONERS IN LUNACY, 1910.[1]

ON January 1st, 1910, the number of certified insane persons under care in England and Wales was 130,553, a number exceeding that recorded on Jan. 1st, 1909, by 1766. The average annual increase for the ten years ending on Dec. 31st, 1909, was 2394, so that the increase for the year 1909 was 628 below the average of the decennium. The increase is lower than any yearly increase since 1901. Although the estimated population in 1910 is 12·2 per cent. above that in 1900 and that of the insane 22·4 per cent. above that in 1900, yet in the rate of increase during 1909 there is a marked approximation between the two series, that of the general population being reckoned to be 1·16 per cent. and that of the insane 1·37 per cent. If the rate of increase of the insane should continue to fall it may shortly be expected to come down to the same level as that of the general community. Taking the number of patients admitted annually and calculating the ratio that they bear to the population, it appears that from 1869 onwards the ratios, whilst fluctuating from year to year, have risen from 4·71 per 10,000 in 1869, the lowest recorded, to 6·93 in 1902, from which year there has been an almost regular decline to 6·09 in 1909, which is nearly the same as the ratio in 1899. On the figures of 1869 the increase of the ratios, which was as much as 47·1 per 10,000 in 1902, fell to 29·3 in 1909.

There were placed under care during the year 1909 21,764 patients, being 480 fewer than during the previous year. Of the number admitted there were 18,346 first admissions. The number of those discharged recovered was 7831, giving upon the total admissions a recovery rate of 35·98 per cent., being 9·6 higher than the rate for 1908 and 0·92 below the average for the ten years 1900 to 1909 inclusive. The rate for females was higher than that for males. Those discharged as not recovered numbered 2186. The deaths numbered 10,138, exceeding the number for 1908 by 446. The death-rate, reckoned on the daily average number resident, was 9·78 per cent., being 0·18 below the average for the ten years. The rate for males was 10·97 and that for females 8·75. The death-rate is more than six times as high as the general death-rate. The ratio of deaths in institutions for the insane, exclusive of those for idiots, per 1000 living was for males 105·2 and for females 84·9. Among the general population in the same year the ratio was 15·7 and 13·7. There appear to be four causes which together account for nearly 45 per cent. of the total number. These are general paralysis, 17 per cent.; tuberculosis, 16 per cent.; old age, 9 per cent.; and dysentery, 3 per cent. The number of post-mortem examinations was 7476, being 77·6 per cent. of the total number of deaths.

In the matter of the allegations made last year as to the annoyance caused by the exercising of patients in the neighbourhood of Epsom, it appears that the Asylums Committee of the London County Council has drawn up regulations so that the public may be safeguarded and, at the same time, that all patients who are fit for it may have frequent opportunities for that change of scene in the outer world which is for many of them desirable. The regulations are comprehensive and reasonable.

The Commissioners have devoted some pages of their report to an interesting consideration of the exceptional prevalence of dysentery in asylums. It appears that only in about one half of the asylums of England and Wales is dysentery so prevalent as to justify its being regarded as endemic or indigenous, that in no small number of the remainder of these institutions the disease is very rarely met with, and that in a few it does not appear at all. The occurrence of the disease in epidemic outbreaks is by no means universal, and some asylums where the incidence-rate is high are quite free of them, though, on the other hand, such outbreaks have occurred in asylums where previously cases have been few and sporadic. These epidemics seem to be best explained on the hypothesis of varying infectivity, favoured, perhaps, by local conditions. Many asylums are comparatively exempt from dysentery, and in view of this it cannot be asserted that such conditions as overcrowding or defective sanitation can of themselves determine its occurrence, however much they may conduce to its persistence when once it has gained an entrance. The chronically insane are more prone to the disease than are others and appear to furnish appropriate soil for the virus which, as well as other essential factors, must be postulated.

Reference is made in the report to a letter received from the Medico-Psychological Association concerning post-graduate instruction in psychiatry, and the Commissioners express themselves as being in warm sympathy with the principles enunciated. It has long been felt that adequate and systematic instruction in the science is in this country defective, or indeed almost absent, and the evils resulting become more conspicuous every year. The Association has become impressed with the desirability of the establishment of a special diploma on the lines of those of public health and tropical medicine and is of opinion that its institution would impose a high standard of acquirement in the officers of asylums, would stimulate the scientific study of insanity, and would have an effect in widening and deepening knowledge of the subject.

In a supplement to the report is contained a series of abstracts of papers published and work done in various asylums by a large number of investigators.

[1] London: Eyre and Spottiswoode. Price 2*s*. 11*d*.

FIFTY-SECOND ANNUAL REPORT OF THE GENERAL BOARD OF COMMISSIONERS IN LUNACY IN SCOTLAND.

ON Jan. 1st of this year there were 18,337 insane persons in Scotland of whom the Board had cognisance. The general results for the year 1909 compared with those of the previous year are as follows: 1. There was a total increase of 111. This increase is regarded as the product of an increasing population, and is the smallest recorded since the establishment of the Board. It is more than accounted for by the decreased number of patients removed from the register by discharge, since it occurred in spite of a falling admission-rate and a rising death-rate. Admissions numbered 3249, and of these 496 were private patients, or 114 less than in the preceding year; and 2753 were pauper patients, or 160 less than in the preceding year. It appears that, notwithstanding the increase in proportion to population of insane persons, officially known as such, in the past five years the production of insanity as shown by admissions to the register has not risen, but has, on the contrary, materially decreased. What has happened is, in the apt comparison used in the report, precisely analogous to the case of a reservoir which, notwithstanding a diminished inlet of water, will fill to overflowing if the outlet is more than equally diminished. The discharge-rate, which in the period 1881–85 was 177 per 1000, has in the last five years fallen to 121. This is attributed by the Board to such reasons as the growing tendency of the public to regard asylums as merely a special form of general hospital, and the consequent reluctance of relatives to receive patients back to their homes unless complete recovery has taken place; the larger proportion of old or physically disabled patients who are when admitted broken down in mind and body beyond hope of recovery; and the growing inactivity or indifference on the part of many parochial authorities with regard to the removal of unrecovered patients who have ceased to derive benefit from asylum residence.

The number of patients discharged was 3156. Of these, 215 were private patients, this number being 19 less than in the preceding year, while the pauper patients were 151 below the number for the preceding year. While the proportion of recoveries among private patients has varied from one year to another, it has shown no certain indications of falling off. Among pauper patients a continuous decrease is recorded. The recovery rate has, in the opinion of the Board, been unfavourably affected by the increased use of observation wards connected with the parochial hospitals of several large parishes, which receive persons suffering from passing attacks of mental disorder, of whom some, in the absence of such wards, would have been removed to asylums and would have been discharged recovered shortly after admission. Deaths among private patients numbered 209, and among pauper patients 1184.

The report this year contains the quinquennial retrospect that the Board is accustomed to make. Certain important and reassuring conclusions are reached. While it appears that the number of patients on the register has increased during the last five years, yet the increase is greatly below that of any quinquenniad during the previous 25 years. The increased number of patients found upon the register is due to accumulation caused by a fall in the number of patients discharged to an extent which has outbalanced the effects of a lowered admission-rate and a higher death-rate. The occurrence of insanity, as shown by admissions to the register, in proportion to population shows a marked decrease, confined to no particular part of the country, throughout the past five years.

THE WEST OF ENGLAND EYE INFIRMARY, EXETER.—Earl Fortescue, on Sept. 21st, formally opened the new "centenary" wing of the West of England Eye Infirmary in the presence of a large gathering. The new building consists of male and female day-wards, children's day-ward, servants' dormitories, children's playground on a flat roof, kitchens, &c. The cost of the undertaking was £3000, and the whole of this sum has been raised. The West of England Eye Infirmary performs a most useful work in the "Ever Faithful City," for during the hundred years it has been established over 120,000 persons have been treated.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Bristol.—The growth of this important city, largely by extension of its limits and absorption of relatively rural areas, is well exemplified in the current annual report of Dr. D. S. Davies. In 1891 the area of the city was 4538 acres, the population 222,049, and the density 48·93 persons per acre; in 1909 the area had quadrupled itself at 17,289 acres, the population was estimated at 377,642, and the density had been reduced to 21·84 persons per acre. In 1897 a population of 85,800 was added to the city, and in 1904 one of 13,443. The corrected death-rate for the year 1909 was 13·76 per 1000, and the infantile mortality only 101 per 1000 births. The Notification of Births Act has not yet been adopted, nor have any health visitors been employed. But on Nov. 5th, 1909, a committee of ladies opened a school for mothers whereat demonstrations on the bathing and dressing of infants are given and similar matters discussed. Every Friday a lady medical practitioner attends and gives advice. "Health Talks" are also given at the mothers' meetings in different parts of the city. The promoters of these movements must not be discouraged if the efforts are followed by a rise in the infantile mortality, as the rate for 1909 was a remarkably low one, and due mainly to climatic conditions which may not be repeated. A very instructive account of the small-pox in Bristol during 1909 is to be found in the report before us, and it may be read with profit by every medical officer of health in the country. There were in all 39 cases with 9 deaths, the outbreak commencing in December, 1908, in the person of a corn porter who apparently contracted the disease while at work discharging grain from a steamship from the Sea of Azov. The cases arranged themselves into three groups, but the origin of all the groups is not clear. What, however, comes out in very pronounced fashion is the high infectious power of the disease and its long striking distance. For example, one man before the nature of his illness was ascertained travelled for three miles in a tramcar, and in this manner came in contact with 395 persons who had to be kept under observation during the whole period of incubation. The patient himself died, and he infected his daughter-in-law, a charwoman, a workman at adjoining premises, and a fellow lodger, who in his turn infected two other lodgers and then a bootmaker. In another instance a man at a village some seven miles from Bristol sickened with *variola nigra*, which condition was diagnosed as *purpura*. He was unfortunately conveyed to a general hospital in Bristol, where he died from "acute nephritis," and his body was returned to the village for burial. This case is known to have infected at least 15 other persons, and indirectly it led to 24 cases with two deaths. Persons who entered the ward in which the patient was being treated were attacked, and the two men who carried the coffin to the grave as well as three others who attended the funeral developed the malady; in fact, the disease manifested an infectivity which goes far to suggest that the infection was air-borne, since presumably no contact whatever took place either with the coffin or infected articles in several instances. The disease spread almost entirely through the agency of unrecognised cases, and the series as a whole shows the fallacy of relying upon any machinery which excludes vaccination and revaccination. As Dr. Davies observes, this type of the malady was extremely virulent, as there were three deaths from hæmorrhagic small-pox in unvaccinated children, and out of the 39 cases notified 6, or 15·4 per cent., were hæmorrhagic. The intensity was indeed so great that Dr. Davies thinks it threatened to break down the strong barrier of recent vaccination in the case of two of the nurses who suffered from temporary malaise. The total cost of this outbreak was £829 17*s.* 11*d.*, and it is clear that but for the almost superhuman efforts of Dr. Davies and his staff, who made no less than 16,000 inquiries, the bill would have been of much greater magnitude, perhaps even approaching the cost of the West Ham epidemic in 1901–02, which amounted to over £26,000. The corporation subsidises 20 beds at the Winsley Sanatorium for Bristol cases of pulmonary tuberculosis; and the following table is instructive in view of the interest now being manifested in the much debated question of the value of sanatorium treatment. It may be mentioned

as some guide to the methods of selecting cases which is adopted that during 1909 there were 149 persons who made application for admission and of these 75 were admitted.

Year of discharge.	Total discharged.	Alive Dec. 31st, 1909.	Well and working capacity maintained.	Whereabouts unknown.	Dead.
1905	45	16	12	6	23
1906	67	21	19	10	36
1907	68	37	33	15	16
1908	78	46	43	9	23

Dr. Davies is performing a useful public service in publishing the statistics in this fashion.

County Borough of Oldham.—Dr. James B. Wilkinson gives grounds for estimating the population of Oldham at over 150,000, as against the Registrar-General's estimate of 143,301, and it is important to bear in mind the fact that the annual rates for 1909 are based on the latter figures. The birth-rate was 27·4 and the corrected death-rate 19·0 per 1000 in each instance, while the infantile mortality was 119 per 1000 births, which is 18 per cent. below the previous lowest record. During 1909 an inquiry was undertaken in one of the wards with respect to the influence of the employment of married women on infant life. Although the number of births in the population under consideration was too small for reliable inferences to be drawn, the investigation, for what it is worth, supports the view that the industrial employment of women exercises no very harmful effect upon the infant. It was shown that in Oldham at least 85 per cent. of the mothers who are engaged at the mills relinquish work at least a month before confinement, while in the case of other forms of employment 80 per cent. worked up to the last week. After confinement nearly 60 per cent. of the mothers did not resume work during the year, only 4 per cent. resumed work at the end of a month, and 20 per cent. within two months, these latter being for the most part compelled to return to work from lack of funds. The facts elicited tended to show that as a rule the married woman gives up work altogether after her first confinement. The death-rate from pulmonary tuberculosis was 1·4 per 1000, which was the lowest on record, except in 1906, when it was 1·3 per 1000. There has, in fact, as in almost every other town, been a gradual lowering of the death-rate from this disease for many years past. With the introduction of the tuberculosis regulations as regards Poor-law cases it was found desirable to obtain compulsory powers for disinfection and cleansing, and provision towards this end was made in a local Bill then before Parliament. But the Parliamentary Committee refused to grant the powers asked for without compulsory notification, which came into force at the beginning of November, 1909. With a view to facilitating treatment one block of the small-pox hospital has been set aside for the use of patients suffering from pulmonary tuberculosis, there being accommodation for nine male and nine female patients. The experience so far gained has been in accordance with that obtained elsewhere—that is to say, that the patients have often made considerable progress even during cold weather with three or four feet of snow on the ground. The hospital is at a level of over 1000 feet above the sea, but is sheltered by hills from the north and east winds. The fact that the cold weather and snow did not affect the patients prejudicially is no matter for surprise to anyone familiar with the conditions existing in the high Alps during the winter months, even at altitudes such of those of St. Moritz and Davos of 5000 to 6000 feet above sea level. The charge made at Oldham varies according to the income of the family from *nil* to 3*s.* 6*d.* and upwards, and the guardians have sent in four cases at a charge of 35*s.* a week. The cost of maintenance is 32*s.* 6*d.* per week when all the beds are full. The majority of the cases gained greatly in weight, but in several instances where this gain took place there was but little improvement in the lung condition. No comments are made as to the presence or absence of tubercle bacilli on admission and discharge. The water-supply of Oldham is derived from upland gathering grounds and is very pure. It has, however, a distinct plumbo-solvent power, and to correct this the water is collected from the land as rapidly as possible and treated with carbonate of lime, which appears to be effectual. Parliamentary powers have now been obtained for utilising the water pumped from a disused colliery.

County Borough of Bury.—Dr. Robert Burnet is able to announce in his annual report that owing to the munificence of Mr. and Mrs. Aitken, who have handed over to the Bury and District Joint Hospital Board their former residence, Holcombe Hall, there will soon be available for the people of Bury an up-to-date sanatorium for consumption. The Notification of Births Act, 1907, which has now been adopted in Bury, is working smoothly, a lady inspector having been appointed to visit the children.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 7692 births and 4235 deaths were registered during the week ending Sept. 24th. The annual rate of mortality in these towns, which had been 11·7 and 12·6 per 1000 in the two preceding weeks, further rose last week to 13·0, and exceeded the rate in any week since February last. During the first 12 weeks of the current quarter the death-rate in these towns averaged 11·6 per 1000, and in London during the same period the death-rate, calculated on the probably over-estimated population, did not exceed 10·8 per 1000. The lowest reported annual death-rates in these 77 towns last week were 4·7 in Leyton, 6·0 in East Ham, and 6·2 in King's Norton, all being suburban districts; the rates in the other towns ranged upwards to 19·4 in St. Helens and in Halifax, 20·3 in Oldham, 20·4 in Dewsbury and 22·7 in Swansea. In London last week the reported death-rate did not exceed 12·0 per 1000. The 4235 deaths registered in the 77 towns last week showed a further increase of 150 upon the numbers in the two preceding weeks, and included 589 which were referred to the principal epidemic diseases, against numbers ranging between 720 and 621 in the four previous weeks; of these 589 deaths, 399 resulted from diarrhœa, 64 from whooping-cough, 42 from measles, 32 from diphtheria, 27 from scarlet fever, and 25 from enteric fever, but not one from small-pox. The mean annual rate of mortality from these diseases in the 77 towns last week was 1·8 per 1000, against 2·2, 1·9, and 2·0 in the three preceding weeks. No death from any of these epidemic diseases was registered last week in Walthamstow, Hornsey, Reading, Coventry, Bournemouth, Burton-on-Trent, or Ipswich; the annual death-rates therefrom ranged upwards, however, to 3·9 in Middlesbrough and in Newport (Mon.), 4·1 in Barrow-in-Furness, 4·5 in Stockport, and 4·7 in Hull. The deaths attributed to diarrhœa in the 77 towns, which had been 527, 462, and 476 in the three preceding weeks, declined last week to 399; they caused, however, death-rates in the several towns ranging upwards to 3·5 in Stockport and in Preston, and 3·9 in Hull and in Newport (Mon.). The fatal cases of whooping-cough, which had been 50 and 56 in the two previous weeks, further rose to 64 in the week under notice; the highest rate from this disease during the week was 1·1 in Blackburn. The deaths from measles, which in the four preceding weeks had ranged between 77 and 51, declined last week to 42, and were fewer than in any previous week of this year; they caused the highest rates 1·4 and 2·8 in Oldham and Tynemouth. The 32 deaths referred to diphtheria showed an increase of 13 upon the number in the previous week, and included 10 in London and its suburban districts, and 4 in Birmingham and King's Norton. Scarlet fever caused 27 deaths last week, against 17 and 18 in the two preceding weeks; these included 6 in Liverpool, corresponding with the number in the previous week; they were proportionally most numerous, however, in Walsall and in Huddersfield. The 25 deaths referred to enteric fever also showed an increase upon recent weekly numbers; 12 occurred in London (against 3 and 6 in the two previous weeks), and 2 in Bolton. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased in the five preceding weeks from 1423 to 1509, had further risen on Saturday last to 1560; 210 new cases were admitted to these hospitals during the week, against 183 and 201 in the two preceding weeks. The 1118 deaths from all causes in London last week included 123 which were referred to pneumonia and other diseases of the respiratory

system; they showed a decline of three from the number in the previous week, and were 20 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 37, or 0·9 per cent., of the deaths registered in the 77 towns during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Leicester, Salford, and in 50 other smaller towns; the 37 uncertified causes of death in the 77 towns included 7 in Birmingham, 5 in Liverpool, 4 in Preston, 3 in Sheffield, and 2 in South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 800 births and 494 deaths were registered during the week ending Sept. 24th. The annual rate of mortality in these towns, which had been equal to 13·0 per 1000 in each of the two preceding weeks, rose last week to 13·6. During the first 12 weeks of the current quarter the death-rate in these towns averaged 12·8 per 1000, and exceeded by 1·2 the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns in the week under notice ranged from 9·5 and 11·9 in Paisley and Edinburgh to 22·4 in Perth and 23·4 in Greenock. The 494 deaths from all causes in the eight towns last week exceeded by 21 the number returned in each of the two preceding weeks, and included 72 which were referred to the principal epidemic diseases, against 93, 69, and 78 in the three preceding weeks; of these 72 deaths, 47 resulted from diarrhœa, 10 from diphtheria, 5 from scarlet fever, 4 from whooping-cough, 4 from "fever," and 2 from measles, but not one from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 2·0 per 1000, the rate from the same diseases in the 77 English towns being 1·8 per 1000. The deaths attributed to diarrhœa in the Scotch towns, which had been 68, 51, and 45 in the three preceding weeks, rose again to 47 last week, of which 22 occurred in Glasgow, 9 in Dundee, 5 in Edinburgh and in Aberdeen, 4 in Paisley, and 2 in Greenock. The 10 fatal cases of diphtheria corresponded with the number in the previous week, and included 4 in Edinburgh and 3 in Glasgow. Three of the 5 deaths from scarlet fever and 2 of the 4 from whooping-cough were returned in Glasgow. The 2 fatal cases of measles occurred in Dundee. The 4 deaths referred to "fever" corresponded with the number in the previous week, and included 3 in Glasgow and 1 in Greenock; the 3 in Glasgow were certified as enteric, and the 1 in Greenock as cerebro-meningitis. The deaths referred to diseases of the respiratory system in the eight towns, which had been 42 and 58 in the two previous weeks, further rose to 64 last week, and exceeded by 5 the number in the corresponding week of last year. The causes of 17, or 3·4 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 647 births and 387 deaths were registered during the week ending Sept. 24th. The mean annual rate of mortality in these towns, which had been equal to 15·1 and 17·0 per 1000 in the two preceding weeks, further rose to 17·5 in the week under notice. During the first 12 weeks of the current quarter the annual death-rate in these Irish towns averaged 16·2 per 1000; the mean rate during the same period did not exceed 11·6 in the 77 largest English towns and 12·8 in the eight principal Scotch towns. The annual death-rate during last week was equal to 21·4 in Dublin, 16·3 in Belfast, 16·4 in Cork, 10·8 in Londonderry, 12·3 in Limerick, and 23·4 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns did not exceed 14·2 per 1000. The 387 deaths from all causes in the 22 town districts last week showed a further increase of 12 upon the numbers returned in recent weeks, and included 58 which were referred to the principal epidemic diseases, against 43 and 61 in the two preceding weeks; these 58 deaths were equal to an annual rate of 2·6 per 1000, the rate from the same diseases last week being 1·8 in the 77 English towns, and 2·0 in the eight Scotch towns. The 58 deaths from these epidemic diseases in the Irish towns last week included 45 from diarrhœa, 6 from measles, 4 from diphtheria, 2 from whooping-cough, and 1 from enteric fever, but not one from small-pox. The deaths attributed to diarrhœa, which had been 38 and 48 in the two previous weeks, declined again to 45 in the week under notice, and included 21 in Dublin, 13 in Belfast, 4 in Cork, and 2 both in Londonderry and Waterford. Of the 6 fatal cases of measles, 3 occurred in Dublin and 3 in Belfast. Three of the 4 deaths from diphtheria were returned in Dublin, as was also the death referred to enteric fever. The deaths in the 22 towns last week included 54 which were referred to pneumonia and other diseases of the respiratory system, against 38 and 47 in the two preceding weeks. The causes of 9, or 2·3 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·9 per cent., and in the eight Scotch towns it was equal to 3·4 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: Fleet-Surgeons: A. Maclean to the *Jupiter*, on recommissioning, and H. S. Burniston to the *Britannia*, on recommissioning. Staff-Surgeons: C. E. C. Stanford to the *Jupiter*, on recommissioning; W. H. O. Garde to the *Minerva*, on recommissioning; A. J. Hewitt to the *Jupiter*, additional, on recommissioning; A. G. Eastment to the *Gloucester*, on commissioning; and W. H. Daw to the *Isis*, on recommissioning. Surgeons: F. G. Goble to the *Minerva*, on recommissioning, and S. L. McBean to the *Britannia*, on recommissioning.

ROYAL NAVAL VOLUNTEER RESERVE.

William Alexander Milne to be Surgeon (dated Sept. 22nd, 1910).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd London (City of London) Field Ambulance: Captain Ernest B. Waggett to be Major (dated Feb. 3rd, 1910).

1st South Midland Field Ambulance: Major Cyril H. Howkins to be Lieutenant-Colonel (dated August 22nd, 1910).

For attachment to Units other than Medical Units.—Lieutenant Charles Corfield, from the 3rd South Midland Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated August 17th, 1910).

A NEW NAVAL GYMNASIUM.

The new Physical Training School, erected at a cost of £20,000, close to the Royal Naval Barracks at Portsmouth, was formally opened on Sept. 22nd. The gymnasium is equipped with all the most approved apparatus for instruction.

TERRITORIAL NURSING AND RED CROSS NOTES.

On Sept. 8th a branch of the British Red Cross Society was formed at Uttoxeter. Colonel J. H. Jelf, C.M.G., who explained the objects and aims of the Red Cross movement, said that there was a good deal of misconception on this subject. Some people imagined that it was a political society, but it was simply and solely an association for reducing, as far as possible, the misery, unhappiness, and suffering which invariably followed in the course of war in any country. Whatever else might be said of Mr. Haldane's scheme, it had prepared a framework—and a framework which he, for one, considered admirable—for the defence of the country. The ladies could help in the defence of the country by joining the Voluntary Aid Detachment, by which they would relieve the suffering of soldiers and sailors, and especially the suffering of the members of the Territorial Forces, in the event of their being called upon for active service.

HEALTH REPORTS OF FOREIGN NAVIES.

Other nations are very deliberate in producing their reports on the health of their navies. That of the Japanese navy for 1907 was issued in May, the Italian report for 1905 and 1906 was published only in July, while the Blue-book for the British navy for 1908 is already out, and the German report

for 1906–07 appeared a year ago. Of these, the German is particularly interesting with its well-prepared clinical and etiological accounts of the diseases observed. The Japanese report, very well printed, and in English, has less clinical interest, but its two striking diagrams are very useful, exhibiting graphically and immediately the causes of the chief losses to the service by invalidings (phthisis, 167 men; pleurisy, 103; injuries, 18); and by deaths (typhoid fever, 34; suicide, 30; burns, 27; phthisis, 27; pleurisy, 9). Their total force was 40,429 men, of whom, per 1000, 4·7 died, and the daily sick-rate was 58. The number "sick" appears large, but includes men doing their work while attending for treatment as well as men on light duty. The recruiting tables show the average height, weight, chest expansion, hand grasp (left and right), &c., of the recruits from the various Japanese prefectures. These should in time be of great anthropological interest. The weight of the men in the fleet (average 129¼ pounds) is obtained from the weighing of 38,029 men in March, when their weight is a maximum, and also in September, when it is a minimum. This lessened weight after summer is noted in the German report, and ascribed to the strenuous life during the manœuvres. The Japanese report nowhere indicates the age incidence of the disease which occurred. This is fully stated in the very elaborate Italian report; indeed, in too great detail to be of much use. But these lavishly provided tables are interesting, showing the incidence of disease on the various groups of officers and men, executive officers, doctors, stokers, ship's stewards, and so on, both according to age and month by month. It is surprising to find (pp. 160–161) that there were 201 officers in 1905 between the ages of 20 and 25, but in 1906 only 56, making one wonder what became of the others since the preceding year. The preliminary remarks are mainly confined to the statistics repeated later in the tables; it would be more instructive to have essays on the cause and treatment of the diseases as in the German report. There were in the Italian navy in 1906 27,358 men, of whom per 1000 3·47 died, and the daily sick-rate was 49. The parallel figures were for Germany in 1906–07, 45,776; 2·4; 27. for the British navy in 1907, 108,740; 3·35; 29. Venereal disease causes 30 to 40 per cent. of the daily sick list of all four navies, of which syphilis is roughly one-third. The loss from tubercle is most marked in Japan and Italy. Japan besides lost many men from pleurisy. If in the periods stated the total loss of service from tubercle be calculated by Gatewood's method,[1] which associates sick list, invalids, and deaths, and gives perhaps a better measure of the morbidity than any other, they work out at: Japan, 3·3 men daily per 1000; Italy, 2·5; England, 1·8, and Germany, 1·2. But these figures cannot be at all exactly weighed against one another when we are without information as to the age distribution and the periods of service in each case. It would be easier to compare the health conditions of other navies if they all published an abstract of their statistics like that in the English Blue-book, Total force, No. 1, which gives the best statistical summary.

[1] See review of his book on Naval Hygiene, THE LANCET, Dec. 4th 1909, p. 1673.

HEALTH OF DEVON IN 1909.—The medical officer of health of Devon (Mr. G. Adkins) in his annual report for 1909, which has just been issued, states that during the year 9007 births were registered, giving a birth-rate of 20 per 1000, compared with 20·3 in 1908. 6047 deaths were registered, the death-rate being 13·4 per 1000, against 13·6 in the preceding year. The death-rate from infectious diseases was 0·34 per 1000. 1490 cases of notifiable diseases occurred, giving a rate of 3·3 per 1000, the same as in 1908. Three cases of small-pox were notified, two of which were brought to the port of Plymouth. 708 cases of scarlet fever were notified, 474 of diphtheria, and 93 of enteric fever. 412 deaths were due to pulmonary tuberculosis, compared with 479 in the previous year. 133 deaths occurred from other forms of tuberculosis, against 142 in 1908. Mr. Adkins states that 327 midwives were registered in the county during the year, against 350 in 1908, and of these 75 were certificated. The district medical officers of health perform the duties of the inspection of midwives.

"Audi alteram partem."

PELLAGRA IN EGYPT.

To the Editor of THE LANCET.

SIR,—The great interest now taken in the etiology of pellagra encourages me to put forward the views which I have long held on the subject, and which may be worthy of attention by the Commission which is, I believe, at work in Egypt. My remarks apply only to pellagra in Egypt, as I have had no experience of it in other countries. During the winter of 1902 I was resident medical officer of Kasr-el-Ainy Hospital, and showed several of the visitors to the Medical Congress round the wards. While so engaged the first doubt as to the reality of pellagra as a definite disease arose in my mind. Professor Bouchard of Paris was one of the visitors, and at his request I showed a case of pellagra which he said was not the same thing as he had seen in the Landes. This statement, coupled with the opinion of the late Dr. Seymour Toller, that pellagra was nothing but a rash due to wind and dirt acting on the skins of the poor and ill-nourished, made me wonder how far the generally accepted opinion was correct. Another point which served to strengthen my doubts was that the rash disappeared, without active treatment, after a day or two of hospital life, but without any corresponding amelioration of the patient's condition. After more than a year of large opportunity and close observation, I was convinced that the patients who showed symptoms, attributed to the eating of diseased maize, were invariably suffering, and had for prolonged periods suffered, from one of the numerous debilitating diseases which prevail in Egypt. I refer chiefly to ankylostomiasis and bilharziasis, though multiple infections with these and other worms are exceedingly common.

A report on three fatal cases of pellagra, with an account of the examination of the spinal cords, was published by Dr. F. M. Sandwith in 1901 in the *Journal of Pathology and Bacteriology*, and in each of these cases there was some distinct pathological lesion in addition to the skin condition. In Case 1 there were 200 ankylostoma worms and the patient died from cerebral hæmorrhage. The examination of the cord showed marked pallor of the posterior median column with a root degeneration at the level of the first lumbar root. This patient had great anæmia and an enlarged malarious spleen. Case 2 was extremely anæmic, had markedly cirrhotic kidneys, and weighed 67 pounds. There is no record in this case that worms were found at the post-mortem examination. The examination of the cord showed well-marked degeneration of the posterior columns, but in view of the general wasting of tissue it is not to be wondered at that there was some alteration from the normal in such highly specialised tissue as the nervous system. Case 3 had been ill for four years and in this time had had ankylostomiasis, and on admission his fæces contained eggs of uncinaria duodenalis, ascaris lumbricoides, and distomum heterophyes. His weight was 109 pounds. He died from acute pericarditis, and Dr. Batten, who examined the cord, reported it as normal.

It is quite clear from these cases that there is no definite pathological picture in pellagra, but I submit that all the changes reported are compatible with a condition of prolonged infection which produces profound anæmia. The excellent illustration which faces p. 314 of Scheube's Diseases of Warm Countries depicts a characteristic pellagrous rash, but it also carries with it the typical appearance of a patient suffering from one of the common worm infections. On p. 34 of the fifteenth annual report of the Egyptian Hospital for the Insane the following sentence apppears: "Nearly every case of pellagra suffers from bilharzia disease, very many from ankylostoma also, and very many from extreme favus of scalp," &c.

In a letter recently received from the Medical Registrar of Kasr-el-Ainy Hospital, Dr. H. B. Day, it is stated that out of 80 cases of pellagra 54 had demonstrable evidence of other infections in which ankylostoma predominated; that these figures only record the leading

clinical characteristics; and that a more thorough investigation would undoubtedly show a greater prevalence of concomitant infection. In this connexion I might point out that some cases of bilharziasis do not pass eggs either in the urine or fæces. It is evident that "concomitant infection" is exceedingly common, but to my mind this so-called "concomitant infection" is the real infection, and the rash which has called attention to the patient is nothing more than evidence of exposure to sharp winds of the skin of a person in an extremely debilitated condition. The patients reported on by Dr. Sandwith all died from some definite and well-known disease, and neither the pathological changes recorded by him or described by Scheube, who follows Tuczek, are sufficiently definite to convince the sceptic that a pathological entity is being described. The quality of nutrition supplied to the tissues by the blood stream in these cases of severe and prolonged worm infection is not likely to be productive of a high standard of health or efficiency, and it is to me by no means surprising that there should be decay of the more specialised tissues as shown by altered reflexes and mental degenerations. It is stated in Scheube's book that "Winternitz goes so far as to deny the existence of pellagra as a specific disease peculiar to a limited area. What is described as pellagra is in his judgment only the conditions of disease induced by want and misery." I am only at variance with this opinion in that I look on some active disease as a necessary factor in the production of the pellagrous condition.

I should like to make my position quite clear by stating that in my opinion pellagra in Egypt is only a rash arising in patients who have been the subjects of prolonged anæmia, and that it is in most cases due to persistent worm infections, and occurs in the worst cases of these infections in association with poverty and malnutrition. In support of this opinion I produce (1) the three fatal cases reported by Dr. Sandwith, in all of which some cause such as I have described was at work; (2) the fact that the rash disappears after a few days of hospital without active treatment; (3) that a large number of so-called pellagrous patients carry the active cause of their anæmia still with them in the shape of ankylostoma worms, &c.; and (4) that the typical pathological picture of pellagra is what one would expect in cases of prolonged and profound anæmia. Pellagra in Egypt may, I think, be neglected except in so far as it indicates a severe anæmia caused in most cases by a parasitic infection. It is on these terms useful as a symptom, but has, I consider, no claim to be ranked as a disease.

I am, Sir, yours faithfully,

V. S. HODSON, M.B., B.Ch. Oxon., M.R.C.P. Lond.

Khartoum.

THE REGISTRATION OF THE MEDICAL STUDENT AND THE REGULATIONS OF THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—"What to do with our boys" is as pressing a question now as ever it was, and parents have the same difficulties in guiding and guarding and finding openings for their precious charges as their forefathers most probably did in their own cases. Like many others just at this season of the year I had occasion to scan and puzzle over the regulations laid down by the General Medical Council for the registration of those lads who are seeking to enter the medical profession. With a view of making my arguments clear I have made the following extracts as embodying the principal regulations as to registration. As I understand them, they disclose a glaring anomaly upon which I should like the opinion of parents, masters of the great public schools, and of any others who feel an interest in the medical profession. Now for it.

> The course of professional study after registration shall occupy at least five years. .....
>
> *Every* medical student shall be registered in the manner prescribed by the General Medical Council. ..... Every person desirous of being registered as a medical student shall produce or forward to the Branch Registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has attained the age of 16 years, and has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned earlier than 15 days before the date of registration. In addition to the Universities and Schools of Medicine there are many institutions where medical study may be commenced.

Now I have looked out the first professional examination for the Conjoint Board, for the London University, and for Cambridge University, and find the subjects are confined to inorganic chemistry, physics, and biology. These are subjects which can just as well be studied at institutions other than medical schools as at them, and this has been recognised by the General Medical Council, as it allows study of these subjects at, amongst others, the Polytechnic Institute, Westfield College, Central Technical College, City of London College (day classes), and some others, but not at the great public schools.

Full of belief in the power of the General Medical Council to enforce its regulations, I wrote to the Registrar to ask him to register my son as a medical student, he having passed his London matriculation, and asking him (in my innocence) if St. Paul's School would be recognised as an institution in which the lad could work up for his next professional examination—viz., the Preliminary Scientific. His reply is:—

> DEAR SIR,—In answer to your letter, I have to state that as the Council does not approve of medical study until ordinary school education has ceased, it will not be possible for your son to be registered while he remains at St. Paul's School. He should begin study at one of the institutions on the enclosed list. Yours faithfully,
>
> March 3rd, 1910. H. E. ALLEN, Registrar

The only possible inference to be drawn from this reply is that I must either take the boy away from the school, or he cannot count the year towards the required five—an alternative altogether too serious for me to contemplate.

Of course, what applies to St. Paul's School applies to all the other great public schools up and down the country, and it has a very serious meaning to the parents of those boys at these public schools who are intended to enter the medical profession; who, having passed a preliminary examination in arts, wish to proceed to the purely science portion of their career while remaining at the school—they must take them away. It also has its serious side for the public schools. The authorities of most of these schools have gone to endless expense in fitting up the laboratories of the schools, and in appointing as instructors the most competent science teachers to be found, yet they are to lose these boys just when they are likely to be of credit to the school and most able to avail themselves of the material provided by the school. And the boys themselves, are they not also losers in being thus early thrust as it were into the turmoil of hospital life, in losing the discipline, individual attention, and compulsory attendance consequent on a prolongation of school life for another year or part of a year?

"Cui Bono?" Who does really gain by these regulations? Surely it is not the lad! I am afraid that as a parent I cannot appreciate the concentrated wisdom which produced these regulations, for it does seem grossly unfair that a public school boy who wishes to learn the scientific portion of his work at school, where the staff and equipment are admirable, should be penalised to the extent of losing that year in computing the necessary five years of study—that is, if the regulations I have quoted mean what they say. If they do, I am surprised that the public school authorities have not publicly protested against the arbitrariness (and to my mind foolishness) of regulations which are devoid of benefit to the boy, to the school, to the parent, and to the profession generally. If these regulations regarding registration do *not* mean what they say, and are not enforced or enforceable, the sooner the public and parents of boys intended for the medical profession know it the better.

I am, Sir, yours faithfully,

RICHARD BEVAN, L.R.C.P. Lond., D.P.H.

London, Sept. 1st, 1910.

*** Our correspondent sets out very clearly one side of a difficult question which has been much discussed in our columns.—ED. L.

AN INTERESTING CASE OF APPENDICITIS.

To the Editor of THE LANCET.

SIR,—I venture to send you a history of what happens to a poor devil now and again in regions so far unblessed by the presence of specialists.

More or less a fortnight ago, at 5 P.M., after an ordinary day's work with cases of neurasthenia, syphilis, gonorrhœa, nephritis, lung, heart, skin, &c., the writer was called to see a young German, said to be suffering from colic,

the result of having eaten cucumber salad for lunch. Up to that afternoon he had felt well and had attended his place of business daily without fail, being in the opinion of his friends a marvel of health, as he boasted never to have had a day's sickness in his life. At my visit he complained of nausea and some epigastric distress. His pulse was 72, full, of normal tension; temperature 37° C., respiration 20 per minute. Examination revealed nothing to indicate serious trouble, but as he was somewhat constipated, more to fill a formula than otherwise, a purgative enema was prescribed, to be followed after evacuation by a teaspoonful of paregoric, and the remark, made jestingly, that perhaps to-morrow he might show signs of an appendicitis, and so be *à la mode*. Later in the evening, on inquiring by telephone, information was received that the patient felt much relieved, but would be pleased to have a professional visit next morning.

August 22nd, 7 A.M.: There was found epigastric pain instead of merely distress radiating towards the right iliac fossa and umbilicus; actual vomiting instead of only nausea, but the vomit was not really bilious; temperature, 38·5° C.; pulse 90, of good character; abdomen slightly tympanitic, but no tenderness appreciable over McBurney's point, nor *evidence of muscular defence*. Ordered ice-bag over the right lower abdomen, and promised to call later. At 11 A.M. there was found a swelling deeply situated in the appendical region, apparently about the size of a hazel-nut. Pain was more diffused, but more concentrated over the appendix, and one could appreciate a slight muscular resistance in that region. Diagnosis, "commencing appendicitis," and the writer flattered himself that he had rivalled his friend, Professor Dr. Sprengel of Braunschweig, one of the most modest, but at the same time ablest, surgeons in the German Empire, in a diagnosis *præcox*. Recently he had seen the German *savant* make a diagnosis of appendicitis in a case in which he could not find the slightest grounds, but which an immediate operation proved correct. Preparations were made at once for the operation, and in an hour or two all was ready. The incision chosen was the "para-iliac" of Jalaguier, drawing the skin well over the ilium, so that the cut through the transversalis, &c., might not correspond with the cutaneous opening. When opened the peritoneal cavity was found to have formed a pouch, occupying the right iliac fossa, containing an encysted mass of intestines matted together. The ileum in spots denuded of its epithelium, the cæcum with flakes of pus scattered over its superficies, and behind, bound down by adhesions, lay the appendix vermiformis, swollen, and completely sphacelated, 4 centimetres in diameter and 10 in length. No isolation was possible. At the proximal end, that nearest the cæcum, could be felt a small foreign body which in the necessary and difficult manipulations undertaken to ligate and remove the putrescent mass, escaped capture. The appendix was tied off in three portions, first including the meso-appendix with artery and the highest point of the gangrenous organ in a mass ligature, the stump actually being more cæcal than appendical. This was sterilised by cautery and closed with three sutures, and after cleansing as far as possible the cavity, the wound was half closed in superimposed layers, an aseptic gauze drain was left down to the site of the appendix, and the pouch lightly packed with the same. After arranging a snug abdominal bandage the patient was put to bed. Temperature 37·5° C., pulse 120. The after-history so far as the convalescence is concerned has scarce any importance, yet the following verbatim notes taken by the surgeon himself (as we have no "trained" nurses) may be of interest.

During the operation the patient's wife was taken in labour with her first child, and at 3 A.M. (23rd) gave birth to a fine boy, thus affording a spice of variety to the surgeon.

To return to the husband. He was given at once 5 centigrammes of ext. opii, and not allowed food nor drink for 24 hours, only being permitted to rinse his mouth with iced Vichy water. He passed a comfortable night, with neither pain nor vomiting, but without sleep.

August 23rd, 9 A.M.: The gauze packing and drain removed. Fæcal odour marked, indicating probable fistula. Temperature 36·2°, pulse 88; passed flatus freely; same regimen; dorsal decubitus but permitted leg flexion. 24th: Dressing changed, removed packing but replaced gauze drain. Stercoral odour pronounced and some discharge like meconium. Coffee and milk for early breakfast and occasionally during day. Is taking 1 centigramme of opium ext. three times a day. 25th: Discharge slight but decidedly fæcal. Temperature 36·9° C., pulse 76. Removed drain and found on its extremity the stercolith which had been felt at the operation, but which had evidently escaped into the cæcum. Substituted rubber drain of 1 centimetre calibre. Suspended opium and ordered a gramme of calomel in two doses at half an hour's interval, to be aided opportunely by an enema of a solution of boracic acid. Milk and coffee for food and sips of wine and water. At 2 P.M. patient had a copious painless passage from the bowels. Temperature 36·5° C., pulse 76. Allowed extra pillow so as to half-recline towards the right and thus favour drainage. No desire for food; prescribed polyformiates. Icterus progressive; urine rather scanty and loaded with pink urates. 26th: Discharge from wound very slight, but fæcal in character. The wound has been irrigated every day with hydrogen peroxide and looks healthy, with fine strong granulations. Urine same and icterus also. 27th, 3 A.M.: Chill; temperature 38°; some intestinal distress. Ordered purgative enema; good result. At 9 A.M. condition good; temperature 36·9°. At dressing evidence of fistula almost *nil*. May close spontaneously. At 7 P.M. enormous stool unprovoked, containing residues of matters ingested a week ago. Urine beginning to clear and increase in quantity. 28th: Removed tube, as there is absolutely no discharge; temperature 37° C.; pulse 70; appetite fair; icterus almost disappeared. 29th: Nothing of importance. Certain that fistula has closed. 31st: Patient allowed to leave bed and lie on *chaise longue*. Appetite good and general condition magnificent.

Sept. 1st: External wound closed without secondary suture. Baby paid quite a long visit to his papa, whom we expect to allow downstairs to visit his wife in a day or two. Sept. 4th: Has been carried downstairs. His wife also out of bed. Everything and everybody well.

Résumé.—1. We have here a fresh indication to operate in cases of appendicitis as soon as discovered. The writer mistook in this case the stage of the disease, though he cannot see how he could have helped it. But had he resolved, thinking it a beginning case, to treat it as many advise, medicinally, and wait an opportunity to operate *à froid*, where would he and his patient have been? 2. There is demonstrated the almost constant preference to be given to the oblique iliac incision of Jalaguier over the vertical, whose sole claim for consideration, in most cases, is that by opening the sheath of the rectus a firmer cicatrix is obtained. The oblique incision made as described, with the underlying tissues cut in different planes, gives as firm a cicatrix as can be desired, and, besides, the seat of the evil is at once disclosed. 3. There is shown the beneficent effects of the encystment, which Lejars insists is the tendency in all cases of appendicitis, though, unfortunately, not always found so complete as in the case above described. Without a doubt this provision on the part of nature saved the patient, however much it added to the difficulty in operating. 4. The advantage of opium given after such an operation is worthy of attention. Given judiciously it aided in repair, and did not in the least prevent the elimination of toxins through the liver, as shown by the icterus. 5. The post-factum evidence of intestinal partial paralysis, given by the stool of the morning of the 27th, shows the care nature takes of an injured or inflamed bowel, by holding back the passage of even food. (See experiments after bismuth meals in intestinal surgery by Cannon.) 6. The imminence of a fæcal fistula following when the obstruction in the appendix exists near or at its proximal end. In the above case the meso and appendix were ligated *en masse*, and after sterilisation the serous membrane was stitched over the stump of the cæcum, one might say, with full expectation that the stitches would not hold in the semi-friable tissues. Evidently they did not as a whole, but something probably was gained by this extra care, as the fistulous opening, being so much the smaller, closed of itself. 7. The advantage of giving nothing to eat or drink after such an operation, thirst being assuaged by rinsing the mouth for at least 24 hours, was shown; and also (8) the use of peroxide of hydrogen for irrigation and for facilitating the removal of gauze packing.

The anæsthetic used was Merck's chloroform, by the Edinburgh method, on an Esmarch mask. The writer is too old to take kindly to new-fangled apparatus or newly-discovered means. In over 30 years' practice, and a few

thousand administrations without a serious accident, why should he? He believes that more depends on the man than on the method, and when a peculiar case turns up, and he has more faith in his assistant as a surgeon than as an anæsthetist, he gives the chloroform himself and lets the aide have the bistoury.

I am, Sir, yours faithfully,

Guatemala, C.A., Sept. 8th, 1910. J. H. ARTON.

ON THE NOTIFICATION OF CONSUMPTION.

To the Editor of THE LANCET.

SIR,—In reply to "Forensicus" in your issue of Sept. 10th, I should like to state that the questions I put to him were not meant to puzzle, but to show that the compulsory notification of consumption was not only impracticable but impossible, apart from the difficulties that would require to be contended with if it was impartially enforced on all classes of the community. "Forensicus" seems to foresee this for himself, for he pleads for compulsory notification "according to circumstances."

It is possible in the near future that we shall see the advocates of compulsory notification attempting to justify themselves by a resort to statistics, but these statistics must be looked upon with suspicion. It may be attempted to show that in towns where compulsory notification has been adopted the disease has decreased in consequence. Although that may appear from statistics to be the case, it will be found to be due in a great measure to evasions resulting from the desire of the consumptive to avoid the stigma and ostracism which have been found to follow public notification.

Between scarlet fever and consumption there is—for reasons which it is unnecessary here to state—virtually no analogy, and therefore to cite scarlet fever in support of his contention is not relative to the issue, beyond stating that the compulsory notification and isolation of that disease have not controlled its incidence even where they have been most rigorously carried out. But for the campaign against consumption—ill-considered in many of its aspects—and arising chiefly out of a desire to secure public moneys for the support of sanatoriums, it is doubtful if the question as to the necessity for the compulsory notification of this disease would ever have arisen.

Under certain conditions I do not doubt the possibility of consumption being conveyed from person to person, but I hold that it is virtually impossible for it to be conveyed under ordinary hygienic conditions or by mere contact. Hence the unwarrantable and exaggerated statements which have been made and reiterated in the daily press as to its infectious nature are to be deprecated not only from the point of view of the sufferer from tuberculosis, but even in the public interest. Unfortunately, the matter is not to end with these panic articles in the press, for we are soon to be confronted with huge blatant posters fixed on every available hoarding, depicting in language of hyperbole the ravages and infectious nature of consumption.

The terrors of compulsory notification of consumption have not been exaggerated. Even without such a measure there are employers who have dismissed servants suffering from consumption, or compelled them to take a prolonged holiday for no other cause than the fear of infection, with the result that the consumptives have been reduced to penury. Further, professional and business men who are known to be suffering from tuberculosis are eschewed in public. Nor does the matter end here even. Mothers have become afraid to stand by the bedside of their own children, and in other instances the consumptives have been virtually cut off from all intercourse with their own families. Yet I venture to say that few, if any, medical men have ever seen a case of consumption follow another in the same family, living under reasonable sanitary conditions, that could not be satisfactorily accounted for in another way than by contact. The causes of consumption are so complex.

The campaign against consumption has ended in a war against the consumptive. The initial objects in that campaign have been for the most part discarded. The consumptive as a consequence is being repelled instead of being attracted to seek advice at a time when it is possible to bestow upon him lasting and material benefit. Let "Forensicus" as a layman take it to heart that the consumptive needs compassion, for he is a sensitive and introspective person. He can be led, but not forced. Finally, let "Forensicus" *as a layman* understand that the incidence or death-rate from consumption in its broadest sense in any country is but an index of that country's sanitary state and the material welfare of its people.

DIFFICULT LABOUR: A CORRECTION.

To the Editor of THE LANCET.

SIR,—I am much obliged to Dr. Herman for his very courteous correction of the mistake I made in reviewing the last edition of his "Difficult Labour." I am in entire agreement with his view that to attempt to stop hæmorrhage from the uterus by applying a "drug" to the vagina is absurd. My mistake is the more inexcusable since I read the passage over twice before remarking on it.

I am, Sir, yours faithfully,

Sept. 27th, 1910. THE WRITER OF THE REVIEW.

"FALLING OF THE WOMB."

To the Editor of THE LANCET.

SIR,—Since sending you the MS. of my article on Procidentia I have obtained notes of two cases which I had previously failed to trace. Will you please publish them as an addendum to my paper and oblige,

Yours faithfully,

Leeds, Sept. 22nd, 1910. JOHN B. HELLIER.

CASE 32.—VIII.-para, aged 52; procidentia for nine years. In December, 1907, anterior and posterior colporrhaphy, with vagino-fixation, were performed. I saw her on July 29th, 1910, and found the result excellent.

CASE 33.—VI.-para, aged 53; severe case of procidentia, with cystocele. Cervix hypertrophied and ulcerated. Sound 4¾ inches. In January, 1908, I performed anterior and posterior colporrhaphy, with amputation of 2½ inches of the cervix and vagino-fixation. On March 10th, 1910, she was reported cured, with no symptoms to complain of.

THE ACTION OF 15 TO 50 CUBIC CENTIMETRES OF CONCENTRATED ALCOHOL ON THE MEMORY.

To the Editor of THE LANCET.

SIR,—So many recent publications on the evils of alcohol are conspicuous for their logorrhœa, bolstered up by second-hand observations and arguments, that it is a relief to turn to such a concise work as R. Vogt's in the June number of *Norsk Magazin for Lægevidenskaben*, 1910, in which the writer gives his personal experience of the influence of alcohol on the memory. His experiments lasted for over six months, and every precaution was taken to avoid fallacies. He chose himself as a subject, being healthy, middle-aged, a total abstainer for the ten preceding years, and without any idiosyncrasy for alcohol. To test (*a*) the mind's power of assimilation and (*b*) the mind's power of reproduction, 25 lines of a translation of the Odyssey were selected every time for their uniformity of length and the absence of refrain. The time taken to learn these lines by heart was noted, as well as the time taken to repeat the same a certain number of times by heart, the rate at which these repetitions could be made being taken as an index to the thoroughness with which the lines had been learnt. The day after the lines had been learnt most were forgotten, but they were quickly relearnt, the mind's power of reproduction playing a greater part than its power of assimilation. The time therefore taken to relearn the 25 lines was taken as an index to the mind's reproductive power. The trials were all carried out in the morning, a quarter of an hour after breakfast, before the day's work had begun. Stimulants, such as tea and coffee, were taken in moderation. The alcohol was taken from 10 to 15 minutes before the trial began and was diluted with fruit juice, which was also drunk on the mornings when no alcohol was taken. The published tables show that 25 cubic centimetres of concentrated alcohol at first considerably prolonged the time taken to learn 25 lines, but that after a month and a half this effect became less marked. Later, when the alcohol was given on an empty stomach even

quantities as small as 15 cubic centimetres of alcohol prolonged the time of learning considerably, as the second table shows.

TABLE I.

Alcohol taken after breakfast.	Number of experiments.	Average time taken to learn 25 lines by heart.	
		min.	sec.
Jan. 20th–March 3rd { Days without alcohol	15	25	58
Jan. 20th–March 3rd { ,, with ,, (25 c.c.)	6	30	35
March 5th–April 28th { ,, without ,, ...	13	21	26
March 5th–April 28th { ,, with ,, (25 c.c.)	10	22	31
April 30th–June 15th { ,, without ,, ...	14	17	57
April 30th–June 15th { ,, with ,, (25 c.c.)	8	19	12
,, 12th–April 20th ,, ,, ,, (50 c.c.)	2	24	48

TABLE II.

Alcohol taken before breakfast.	Number of experiments.	Average time taken to learn 25 lines by heart.	
		min.	sec.
June 17th–August 1st Days without alcohol	10	18	2
,, 19th–June 27th ,, with ,, (25 c.c.)	3	30	35
July 1st–July 30th ,, ,, ,, (15 c.c.)	4	22	59
,, 19th ,, ,, ,, (30 c.c.)	1	38	50

The alcohol taken after breakfast increased the required time by 5 to 7 per cent.; when it was taken before breakfast the time was increased by 69 per cent. The influence, too, of 50 cubic centimetres of alcohol taken after breakfast was less than that of 25 cubic centimetres taken before breakfast. After some months' practice the time required to learn 25 lines by heart was reduced by about one-third, whether alcohol was taken or not. Not only did the alcohol lengthen the time taken to learn 25 lines by heart, but it also lengthened the time taken to repeat by heart the same lines a given number of times, and from this the writer concludes that the lines could not have been so thoroughly learnt under the influence of alcohol. Each lot of lines which had been learnt by heart from Jan. 20th to April 16th were again learnt by heart 107 to 108 days later, when no alcohol was taken. The shorter the time taken to relearn these lines the better must have been the mind's power of assimilation on the first occasion. It was found that those lines which had been learnt under the influence of alcohol took an appreciably longer time to relearn than the others. The table illustrating this point also shows the interesting fact that, after excluding the alcohol days, those lines which after practice in learning by heart took a short time to learn on the first occasion took longer to relearn than those which had cost more time at the first—in other words, "quickly come, quickly go." Since A. Smith's well-known experiments on the influence of alcohol on the memory little work has been done in this particular field, and though Dr. Vogt's results are merely confirmatory of Smith's, the former deserves our heartiest praise for the indefatigable energy which led him to inflict so many thousand lines upon himself in the cause of science.

I am, Sir, yours faithfully,

Sept. 26th, 1910. C. L.

POOR-LAW REFORM: THE COMMISSION'S TWO REPORTS.

To the Editor of THE LANCET.

SIR,—The issue of two conflicting reports by the late Commission has, no doubt, been useful in increasing the interest in the important subjects dealt with. But are not the medical profession, like many other people, taking the details of these conflicting schemes too seriously? When we consider carefully the *personnel* of the Commission we can only regard one report as a judicious compromise by men and women possessed of strong and very diverse views, and the other as the work of a very small body of people whose strong views are not generally acceptable to the community. This being so, it seems extremely improbable that any proposals put before the country by Parliament will coincide with those contained in either report, whether in the form in which they are printed or in the various modifications which we are from time to time informed by their supporters have since been accepted by the authors. But the waste of time entailed in blessing or otherwise one or other of these reports is not so serious as the tendency caused by these essays in partisanship to divide the profession into different camps. It will take us all our time to think out, and agree upon, the best way of arranging the medical treatment of the poor so that the poor shall be properly treated and the doctors be properly paid, which are after all the two main ends upon which we as a profession are called to express an opinion. We cannot afford to follow the example of some laymen engaged in this controversy and seek out the private and political opinions of our colleagues in order to discredit their proposals. Even a *free trade* doctor may be expected to *protect* the interests of the poor, and the most Fabian *Socialist* may generally be trusted to look after his *individual* fee. Time presses, and all unnecessary points of personal controversy must be neglected if the profession is to have its proper influence in shaping Poor-law medical reform.

I am, Sir, yours faithfully,

Sept. 23rd, 1910. PROFESSIONAL UNION.

A VISIT TO THE MUSKOKA SANATORIUMS FOR TUBERCULOSIS.

(FROM A SPECIAL CORRESPONDENT.)

BY the invitation of Mr. W. J. Gage of Toronto, chairman of the executive committee of the National Sanatorium Association of Canada, I visited the sanatoriums for the treatment of tuberculosis at Muskoka.

The Muskoka Lake District.—How the Sanatoriums are Reached.—Their Origin.

The Muskoka Lake district is situated at a distance of 112 miles or so from Toronto. I got on a mid-day express of the Grand Trunk Railway at Toronto, and although a strike was in progress among the workers of the railway, the train travelled smoothly and at a moderately rapid rate. The scenery of the first 50 miles of the route is placid and somewhat uninteresting, but after Lake Simcoe has been sighted the country begins to take on a wilder aspect. On Kempensfeldt Bay, an inlet of Lake Simcoe, ten miles wide, are the towns of Allandale on one side and Barrie on the other. The train makes a detour of the bay, passing within a few feet of the lake, so that one has the opportunity for judging of the remarkable clearness of the water, a characteristic of Lake Simcoe, for which it is widely famed. When the train leaves Barrie a really lovely country is passed through. Glimpses are caught here and there of lakes and streams shimmering in the sun, and forests and rocks border the line on both sides. At length the train pulls up at Muskoka Wharf, at the foot of Lake Muskoka, the most southern of the three large lakes of the district, and what may be termed the entrance to the Muskoka region proper is reached. The region comprises an area of about 10,000 square miles, and is perhaps the most picturesque part of the Province of Ontario. Within this district, which has a mean altitude above the sea of 800 feet, there are nearly 1000 lakes and ponds, connected by innumerable streams. The chief lakes are Muskoka, Rosseau, and Joseph. The region abounds in pine forests, and the soil is of a rocky porous nature.

On leaving the train at Muskoka Wharf I made it my business to discover a launch, which I had been informed plied between the sanatorium and the wharf for the purpose of conveying patients and visitors to and fro. I did not find the launch, but I came across Dr. W. B. Kendall, the physician-in-chief of the sanatoriums, who had come with his speedy gasoline boat to fetch some friends. I gave him the letter of introduction I carried and was quickly in his boat, which can travel at the rate of about 20 miles an hour. The Cottage Sanatorium to which we were bound is some

two miles from the wharf, and it took us but a short time to reach our destination.

The Muskoka Cottage Sanatorium.

There is, and has been for a long period, much pulmonary tuberculosis in Canada, and in 1896 the National Sanatorium Association was founded, the pioneer association of its kind in Canada. Its object is to provide institutions for the isolation, treatment, and cure of persons affected with pulmonary tuberculosis. The Muskoka Cottage Sanatorium was the first institution to be established under its auspices, and is for the treatment of those suffering from incipient tuberculosis.

The main building of the Cottage Sanatorium, the one of which I first caught sight when our boat slackened speed and drew up at the landing, is a striking landmark of Muskoka Lake. It is a large roomy wooden building, its front faced by wide verandahs and surmounted by a tower overlooking Muskoka Bay. It stands on a height, and together with its cottages is placed in a park of 75 acres, chiefly consisting of pine forest. It is sheltered from the north and north-west winds by rocky ridges and pine trees. From the standpoints of scenery, air, and soil the situation seems almost ideal for its purpose. The air is very clear, the mean relative humidity is 70 to 75, and the mean average temperature is 42° F.; the district is very rocky and the soil porous and dry.

The administration building (Fig. 1.) was erected at the joint expense of Mr. W. J. Gage and of the late Mr. Hart A. Massey, both of Toronto, and was opened in 1897 by Dr. H. Barnes, then president of the British Medical Association, which had just met in Montreal. Dr. Kendall shortly after my arrival showed me through the building. It will accommodate 20 patients and contains the sleeping apartments of the management and service of the institution, the household and medical staff offices, the laboratories, the dispensary, reception-room, music-room, and dining-room. There are sun chambers for patients who cannot sit outside on stormy days. I was favourably impressed by the roominess and comfortable appearance of the whole building, and especially by the laboratories, which form a very prominent feature of the institution. Dr. Caulfield is in charge of the laboratories, assisted by Dr. Beattie, and some valuable investigations have been, and are being, undertaken chiefly in studies of complement deviation with a view to the discovery of immunising methods. A collection of animals is kept for the purpose of experimentation and Dr. Caulfield informed me that he intended to make use of young pigs with this object in view. I am happy to be able to state that all the animals looked well and contented and did not seem to have suffered in any way as a result of the use which had been made of them.

The Muskoka Cottage Sanatorium is really a colony for consumptives, and reminded me both with respect to situation and management of another colony for consumptives at Lake Saranac in the Adirondack region of New York State. As at Saranac, the majority of the patients are housed in pretty cottages, built at the expense of private individuals, which are dotted about within easy reach of the administration building. These cottages contain from two to eight sleeping rooms each, and are, of course, one and all fitted with spacious verandahs. The cottage system was established for the sake of ensuring privacy, and also because the patients who live in cottages are not embarrassed by the feeling of restraint and confinement which is apt to oppress those who are massed together in considerable numbers in one building, however large that building may be.

Many patients live in tent cottages, small roofed wooden buildings, which can be occupied by one or two persons. Other patients occupy what are known as "shacks." A building of this kind, designed by Dr. Kendall, is a long one-storey building with entrance in the centre, which opens into a fair-sized room provided with lavatory accommodation, and which is so furnished that it can also be used as a sitting-room. On either side of the sitting-room are placed the sleeping cots. The front of these shacks from the top to within a short distance from the ground has glass shutters which can be opened or closed as the medical attendant may think fit. The accompanying illustrations will convey a good idea of the appearance inside and out of the shacks. (Fig. 2 and Fig. 3.)

It should be mentioned that all the patients of the Cottage Sanatorium have their meals in the large dining-room of the administration building at numerous tables which will each seat from four to six individuals. The food is plentiful and wholesome, but the over-feeding plan is not followed at Muskoka. I partook of meals with the patients and can therefore vouch for the good quality of the food. I likewise slept in a cottage reserved for patients, and can also give testimony as to the comfort and healthfulness of the sleeping quarters. Each patient has a separate room, but there are several large bedrooms, so that if desired two patients may share a room.

Indoor and outdoor amusements at the sanatorium are many. Muskoka Bay is well suited to boating of every description, and fair partridge and rabbit shooting is to be had. In the winter snow-shoeing, tobogganing, skating, and driving are the favourite forms of exercise. There is also a shooting club amongst the patients, and the sanatorium possesses an excellent billiard room.

The medical staff of the Cottage Sanatorium consists of a physician in chief and two medical men who devote their attention largely to laboratory work. The resident nursing staff is fully adequate to the ordinary needs of the institution, but, if required, special nurses can be secured. I noticed that several of the permanent nursing staff were British, and was pleased to learn that nurses of British birth are in request at Muskoka.

The Muskoka Free Hospital for Consumptives.

At a distance of about one mile from the Cottage Sanatorium (Fig. 4), nearer to the railway and to the town of Gravenhurst, is situated the Muskoka Free Hospital for Consumptives. The main buildings are of wood and are located on a rocky ledge above the lower part of Lake Muskoka. The buildings are large and rambling and have been added to as necessity and convenience dictated, and from the very incoherence of their architecture they present an extremely picturesque outward appearance. The sanatorium faces west and south and is protected from the north and east winds by thick pine woods. The matron of the institution accompanied me to every part and was most courteous in explaining matters. The main building contains four eight-bed wards, one of five beds, and one of four, and the patients were mostly women. The wards are lofty, well-lighted, and in the nature of things airy and well ventilated; they are also provided with wide verandahs. The bathroom and lavatory accommodation is adequate. The heating is by steam and the lighting by electricity. There are, in addition, in the main building a reception-hall and sitting-room for patients, physicians' office, throat-room, dispensary, laboratory, and staff quarters; and in a detached annex there are dining-room, pantries and kitchen, and servants' quarters. Another building contains the ice house and cold storage chambers. Most of the male patients reside in shacks, which in all essential details resemble the one already described. The basis of the treatment is open air, and it has been demonstrated that these shacks best fulfil the required conditions.

As at the Cottage Sanatorium the food is wholesome and provided without stint. I saw the patients at dinner at the Free Sanatorium, and remarked that with very few exceptions they seemed to enjoy the meal heartily. The patients are encouraged to take exercise and to do light work. Gardening is a favourite diversion with them, and I was greatly interested in the poultry-raising experiments which are conducted under the direction of a patient. I was shown over the "hennery," as it is termed, and was astonished at the success achieved in rearing chickens under somewhat adverse circumstances. Hawks are plentiful, and of course are a source of danger to the young fowls, but rats which are very numerous are a far greater peril. However, the guardian of the fowls is provided with a gun and with traps of great variety with which to fight the enemy, and his results may be gauged by the fact that he has nearly 1000 fowls in his enclosure, and that the institution is supplied with poultry and eggs from the "hennery."

General Remarks.

The Cottage Sanatorium is for paying patients and the prices are moderate. The Free Sanatorium, as its name implies, is more or less free. However, as is the case in all public institutions on this continent, if a person can afford to pay for treatment or care he does pay. Consequently, at the

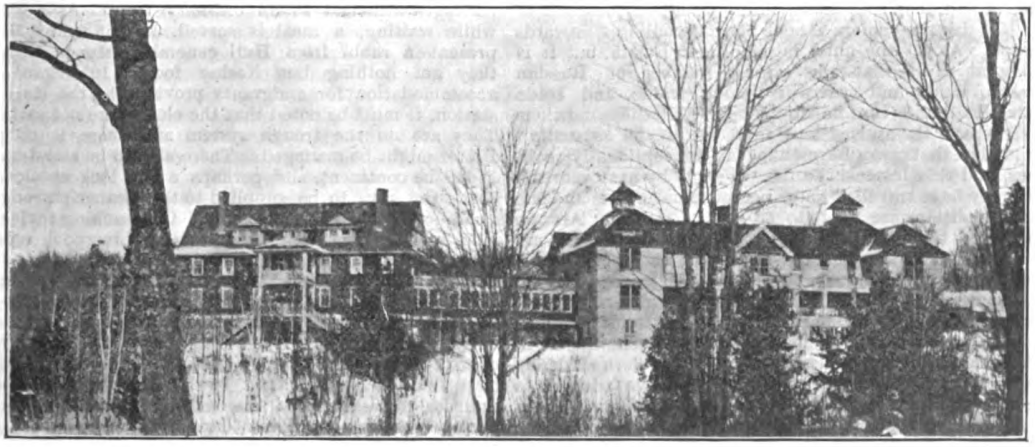
FIG. 4.



Muskoka Free Hospital for Consumptives, Gravenhurst.

Free Hospital for Consumption at Muskoka a large number of the inmates pay whatever sum may be within their power towards the upkeep of the institution. The Free Hospital will accommodate more than 100 patients and is always full to overflowing. The Cottage Sanatorium will hold about 75 patients, and it is rather curious to note that the favourite sanatorium season at Muskoka is in the winter, when the temperature is frequently 20° F. below zero. The physician-in-chief visits the Free Hospital every day, and there is besides a resident medical man. It may be stated that the Free Hospital was opened in 1901 and that the results of treatment therein and at the Cottage Sanatorium have been very encouraging. After an instructive and interesting visit I travelled to the railway depôt by the omnibus in which patients are conveyed to and from the train. I am convinced that few situations can be better for the treatment of incipient pulmonary tuberculosis than Muskoka, and so far as I was able to judge the management of the two sanatoriums I visited leaves little to be desired.

THE CHOLERA MENACE AND THE RESPONSIBILITY OF HULL.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Hull, Sept. 23rd.

IT will be remembered that when, in 1892–3, the last great cholera epidemic spread throughout Europe, reaching from Hamburg to Marseilles and from Calais to Constantinople, the only towns affected in England were Grimsby and Hull. Some isolated cases of cholera occurred even in inland districts, but there were 35 cases at Grimsby, resulting in 21 deaths, and 17 at Hull, causing 12 deaths. These cases were all the more menacing as it was easy to show that most of the patients had been living in very insanitary surroundings, but there was no such clear evidence of contamination imported from abroad. It seemed as if the diarrhœa and the choleraic diarrhœa which then prevailed in an epidemic form might be the forerunners of an epidemic of genuine Asiatic cholera. Thus at Hull, from Sept. 6th to Oct. 20th, 1893, out of a population of 208,639, the 17 cases of cholera resulting in 12 deaths were notified, together with 137 cases of choleraic diarrhœa, giving rise to only 4 deaths, and 396 cases of diarrhœa causing 112 deaths—altogether 550 cases and 128 deaths. The death-rate from diarrhœa in 1893 was 2·27 per 1000 of the population, and the deaths from the seven principal zymotic diseases were equal to 4·01 per 1000. Last year, that is in 1909, the deaths from diarrhœa were only equal to 0·59 and from the seven zymotics to 1·35 per 1000. These figures do not, however, imply that we are safer now than in 1893, for in 1891, before the cholera epidemic began, the zymotic death-rate at Hull was only 1·61 per 1000 and the deaths from diarrhœa 0·60 per 1000. There was a slight rise in 1892 and then the high figures of 1893 were reached, and they constituted the maximum of the last 20 years.

The exceptional heat of the summer in 1893 was doubtless the chief cause of the extensive prevalence of diarrhœa, but it also gave rise to the fear that it would favour the importation of cholera and that Hull and Grimsby would be the doors of entry. To-day the cholera is once more travelling westwards in Europe. As yet the chief mischief is in Russia, but it is precisely at Hull that the largest number of Russian emigrants land, and there is much traffic and trade between Hull and the Baltic ports. Will the conditions of 1893 repeat themselves and shall we escape as easily? It is true that we have had an exceptionally cold summer, and this lessens the danger; but by next year the cholera may have travelled much nearer to our coasts and the climatic conditions are likely to be less propitious. Are we better armed to resist an invasion than we were 17 years ago? It would be very unsafe to rely on the fact that we escaped from serious injury on the previous occasion. So much depends on hazard. An accident may defeat the best precautions, though the better the precautions the less likely the occurrence of such an accident. The question, therefore, that the virulence of the Russian cholera epidemic forces upon us to-day is whether our defensive position is stronger now than in 1893. In answer it may be confidently asserted that, so far as the first precaution to be taken is concerned, we are distinctly in a stronger position. In 1893 the Aliens Act was not in force. This law was not meant as part of our sanitary legislation, but incidentally its application greatly facilitates the medical examination of precisely that class of incomers who are the most likely to bring with them the seeds of cholera.

Under the Aliens Act the shipping companies are held responsible for all the emigrants they bring over. To let one escape is to incur the penalty of a heavy fine. Therefore, on the arrival of a ship all the emigrants are gathered together and the medical inspection does not begin until the officials are assured that no one is missing. Of course, if there is an infectious case it is at once removed to the hospital, the family of the patient isolated, and any persons who have been in contact with the patient are notified to the sanitary authorities of their place of destination. Special care, of course, is now taken in watching for symptoms of cholera. Of the numerous and international crowd of patients treated at the Hull Hospital for Infectious Diseases it appears that the Lascars make the best patients. They are also very grateful. When, on a following voyage, they return to Hull they make a point of going to the hospital and by signs and bows endeavour to express their thanks. Chinamen also make very good patients if nothing is done to offend them. Unfortunately it often happens that some ignorant person indulges in careless, silly remarks, especially about the pig-tails, and if a Chinese patient thinks he is not treated with proper respect then it is difficult to manage him. But the real trouble, and at the present moment the special danger, is in respect to the poor immigrants from Russia. It is true that they are for the most part transmigrants and are merely landing at Hull on their way to Liverpool or Glasgow, where they are to sail for America. Formerly some of these poor people did not have a through ticket, or had been robbed at Hamburg and landed penniless at Hull under the impression that in England the streets were paved with gold. They might be seen wandering about the streets in the hope of obtaining some help. To-day, with the Aliens Act in force, this is no longer possible. Shipowners are very careful not to allow anybody to embark for an English port unless he is in possession of money or a transhipment ticket. Thus it would be difficult nowadays to meet with a stranded emigrant; and though efforts are made occasionally to sell false tickets to ignorant people, all the shipping companies are interested in preventing such fraudulent practices and securing the severe punishment of the culprits. The immigrant who lands in England must prove that he has money and give a satisfactory explanation about himself. Though this was intended to exclude undesirables and to prevent foreigners becoming paupers as soon as they landed, it will easily be understood that it also, if only incidentally, serves to keep better watch over the persons and health of these new arrivals and thus see that they do not introduce such diseases as cholera into this country.

The emigrants who are going on farther are placed in vans or wagonettes and taken to the large sheds and waiting-rooms built purposely for them by the side of the main railway station at Hull. If they are numerous enough a special train is made up for them; if not, they have special carriages attached to an ordinary train. As a rule, and while waiting, a meal is served, and if many Jews are present a rabbi from Hull generally attends to see that they get nothing but Kosher food. In regard to the accommodation for emigrants provided at the Hull railway station, it must be noted that the closets are not satisfactory. They are on the trough system and there is no privacy. Better might be managed. There should be stand-up closets as on the continent, and perhaps a few lock-up closets with seats, the keys to be supplied to the cleaner passengers at a charge of perhaps a halfpenny. On reaching their destination, which in the majority of cases is Liverpool, representatives of the shipping companies meet the train and convey the passengers on board or to lodging-houses specially prepared for them, where they remain till their ship starts. Thus, it will be seen that both the emigrant and the transmigrant are much more carefully looked after and watched than was the case 17 years ago. This, however, is only our first line of defence, and by far the weakest line. No frontier, however keen the watch; no quarantine regulations, even, as in olden days, when prolonged to the

uttermost and cruelly applied, ever succeeded in excluding all disease carriers, whether these were objects or persons. Ships from Russia may be ever so strictly examined at Hull; passengers from Russia coming by Norway and Sweden, or through central Europe, and landing, for instance, at Dover, pass along with others and are not made the objects of special medical examination.

Our next line of defence depends on the perspicacity and promptitude of every medical practitioner in the country. On him rests the responsibility of detecting the first case and of bringing the whole of the sanitary machinery to bear upon it without the loss of a moment. Very probably the fact that this was done with military discipline and lightning speed at Hull in 1893 explains why the sparks of epidemic were so successfully extinguished. Within an hour of notification the patient and his family would be removed and isolated, his dwelling and the drains disinfected. It is doubtful if even after all this time for preparation there are many authorities so well equipped and able to act with the promptitude displayed by the Hull sanitary staff in 1893. In any case, and however perfect this second line of defence may be, it may fail and cases go undetected. Also there is the possibility that persons are carriers of the germs of cholera without being themselves sufficiently affected to attract notice. Thus we are driven back to our third, and by far and away the most important, line of defence, and that is the general sanitation of the country. How far we may rely upon this can scarcely be a question of doubt. We know, and know but too well, that many dangerous insanitary areas and conditions still remain which hold out a permanent invitation for epidemics to visit our shores. On the other hand, we also know that unwholesome places are neither so large nor so numerous as they were 17 years ago. Consequently it may be said that all the three lines of defence are stronger to-day than they were 17 years ago, but that nevertheless there is no absolute security. We are better prepared than in 1893, but we may perhaps not be so fortunate. Accidental circumstances may prove less in our favour.

In regard to general sanitation, though much has been done much remains undone, and this remark applies to the country in general and to Hull in particular. In 1893 the greater number of cases of cholera occurred in Amelia-place, Starch House-lane, and other small streets or courts not far off. This district, lying to the north of the Holderness-road, has not been much improved, but a large factory now occupies the actual ground where several of the cholera cases occurred in 1893. A considerable amount of work has been done since 1893, at which date a serious effort was made to apply the Housing of the Working Classes Acts at Hull. As a result 1030 dwelling-houses were condemned as unfit for habitation and 779 were completely demolished. The remainder were converted into warehouses or were suitably altered and repaired. Several hundred other houses that were of an unhealthy character have been pulled down to make room for street improvements, and owners have voluntarily demolished their insanitary houses so as to erect buildings more in keeping with modern improvements. Thus, it may be said that the sanitary condition of the town has improved. Yet, acting under the Notification of Births Act, the women inspectors' department reports that in 1909 "1276 houses visited (in 1909) were without backways, and the contents of the privy, when emptied, were carried through the house. This must undoubtedly be prejudicial to the health of all the occupants, but more especially so with young infants, whose rapid development during the first year of life calls for the purest atmosphere obtainable if health and vigour are to be secured." Though it is claimed that, under some pretext or another, something like 200 dwellings have been demolished every year during the last seven or eight years, it will be seen from this report to what a large extent houses without sanitary closets are still tolerated; indeed, there yet remain no less than 10,616 such houses in Hull, for the most part in crowded localities. Here excremental matter accumulates in the narrow yards at the backs of the houses, and when it is shovelled up into buckets and carried through the dwelling rooms to be emptied into a cart waiting in the streets this operation naturally causes a terrible stench. If the excrement remains in the privies it occasions a nuisance, and when it is removed it causes a still greater nuisance. If at any time cholera dejecta are thrown into one of these privies the nuisance will become a very serious danger. Obviously short work should be made of such conditions. Proper water-closets must be substituted for these privies, or the whole area condemned. Portable pails, or middens, or privies, or cesspools are all abominations. In any case, they should never be tolerated unless situated at some distance from dwellings, at the farther end of a garden or backyard, where there is a back passage, so that they can be emptied well away from the inhabited part of the premises. It follows that privies are in no wise suited for town dwellings, especially in poor and crowded districts. The fact that privies still survive, and this to the extent of several thousands in the poorest quarters of Hull, just where cases of cholera occurred in 1893, is somewhat disconcerting. Such weak places in our defensive armour may well engender apprehension, but justifiable fears will be of use in helping to bring about the much needed improvements.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The Children's Hospital, Bristol.

THE numerous friends of the Bristol Royal Hospital for Sick Children and Women have been gratified by the intimation received from Sir Arthur Bigge that their Majesties King George V. and Queen Mary have been pleased to become patrons of the institution, thus joining with Queen Alexandra to continue the patronage bestowed for some years by the late King and his Consort.

Proposed Crematorium for Bristol.

At the last meeting of the Bristol city council the proposal to establish a crematorium in Bristol was defeated by two votes. That eventually the proposition will be carried can hardly be doubted, for at present Bristol is practically the only large city without means of cremation.

Barnstaple Education Committee and Treatment of Dental Defects.

At the last meeting of the Barnstaple (Devon) education committee Mr. J. R. Harper, the medical officer, alluded to the large number of school children suffering from defective teeth, and stated that he doubted whether the present arrangements made at the local infirmary would be sufficient to treat all the cases. Some of the committee advised that a sum of money should be voted to the institution for that purpose. One speaker said that it was impossible for ordinary subscribers to the infirmary to give "recommends" to all the applicants who required dental treatment, and he stated that it was a very serious matter for some of the poor who were suffering from illnesses and could not get "recommends" owing to the dental cases. Eventually it was decided to further discuss the subject in committee.

A Public Abattoir for Weston-super-Mare.

At a meeting of the Weston urban district council held on Sept. 21st it was resolved to purchase three acres of land, at a cost of £1500, for the purpose of erecting a public abattoir. The Local Government Board has been interested in the undertaking and quite recently had informed the Weston urban district council that it would decline to sanction any further loans until definite steps had been taken to provide a public abattoir and a refuse destructor.

The Prevention of Tuberculosis.

Earl Fortescue (the Lord Lieutenant of Devon) formally opened at Plymouth on Sept. 19th the exhibition which has been arranged by the National Society for the Prevention of Consumption in association with the education committee of the Devon County Council. There was a large gathering present, amongst others being the Earl of Mount Edgcumbe and several members of the clerical and medical professions. Dr. R. Hogarth Clay, in the course of an interesting address, stated that through the generosity of the Earl of Mount Edgcumbe, Mr. Astor, and others it had been decided to start a dispensary in the "Three Towns" in connexion with the treatment of tuberculosis. A few rooms would be engaged at which medical men would attend at certain stated hours and a nurse would also be engaged. By this means early cases of tuberculosis would be diagnosed and sent to a sanatorium, whilst the advanced cases would be instructed and treated at their own homes.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Provision for Phthisis.

A DISCUSSION took place at the last meeting of the Chorlton board of guardians with regard to the treatment of the phthisical patients chargeable to the Chorlton union. So long ago as January, 1909, a resolution was passed deciding "that special accommodation for phthisical patients chargeable to the union be immediately provided." Immediately, however, is an adverb of indeterminate elasticity as regards time, and so far nothing has been done to convert the words of the resolution into deeds. Some progress, however, was made at the last meeting, for it was proposed by one lady guardian, and seconded by another, to whom should be given the honour they deserve, "That steps be taken to provide a sanatorium or special hospital for the treatment of cases of consumption, the hospital to be chargeable to the Chorlton union." She said that they had enough patients to fill a sanatorium of their own, and suggested the appointment of a committee to carry out her proposal, "which was the most economical way of dealing with the problem." After some discussion, and objection on the part of one member of the board to anything being done until it was seen what would become of a proposal for the consolidation of the Manchester unions, the resolution was adopted. Hitherto these cases have been sent elsewhere for treatment. The chairman remarked that less than two years ago the board approached the corporation on this question, and the corporation promised "to take steps to do something." So far, however, as the board knew, those steps were not taken yet, and the responsibility of making some attempt to save the lives of these poor consumptives rested on the board. It is satisfactory to know that throughout the land determined and well-advised efforts are being made to combat the scourge of consumption. Apart from humane feeling, it is said that one-seventh of the pauperism of the country is due to consumption, so that it imposes a costly burden. The magnitude of the question becomes more apparent if reference is made to Dr. James Niven's special report on this question. He points out that over 1000 deaths per year in Manchester are attributed to phthisis, and assuming that the patients are infective for three years, on an average, before death, there are 3000 cases to be dealt with. Then there are a number of other infective cases with open tuberculous disease, chiefly in children, numbering probably another 1000. He shows that in 1909 the total loss in wages in 1041 cases was £48,129, to which must be added the loss by unnotified patients who are not working, and by patients who were notified in previous years and who are now out of work. It would therefore be worth while to spend a large sum of money if a great reduction could be made in this serious loss. In Manchester there are now 585 beds available for consumptive cases. Dr. Niven suggests the somewhat revolutionary scheme of amalgamation between the three unions of Manchester, Prestwich, and Chorlton, and that the Prestwich union hospital at Booth Hall should be handed over to the corporation to deal with phthisis. In favourable cases under hospital treatment the disease may last many years, so that to deal effectually with the great array of poor consumptives in the more advanced stages "it would be necessary to obtain powers of compulsory detention and to make a provision greatly in excess of any now contemplated." The report suggests that a system of compulsory insurance, such as that adopted in Germany, would meet the requirements of the case; but until such a system is established it would be necessary to provide a sum for the assistance of households invaded by tuberculosis. Dr. Niven thinks that £5000 would go far to meet such a need. He estimates the total cost per year, including hospital accommodation, public instruction, &c., at £21,000. This scheme will take some little time before it is received very cordially by the general public, but if when thoroughly carried out it were to drive tuberculosis from our midst it would prove not only life-saving but economical. It is not everywhere, however, that by-laws and regulations have advanced to present-day requirements. A few weeks ago, at a meeting of the Bolton council, Dr. J. H. Thompson said that as to dealing with consumption with the building by-laws as they were the authorities were as helpless as little children, and he spoke of them as a standing disgrace. He said, what seems almost incredible, that "in houses being built to-day the sleeping rooms were not a particle better than the cellars of ancient times." He considered it high time "to say that dwellings should not be built to foster and generate disease." Building by-laws have a good deal to answer for, not only in Bolton but in many other places.

Fatal Operations.

On Monday an inquest was held at Preston on a case where the patient died three hours after an operation for intestinal obstruction. The senior house surgeon at Preston Infirmary said that if the operation had not been performed the man could not have lived more than a few hours, an operation being his only chance of life. It seems that the case had not been reported to the coroner, but, having heard of it, he considered it his duty to hold an inquest. The house surgeon, in answer to the coroner, said that during the three years he had been at the infirmary there had been about a dozen such cases which had not been reported to the coroner, as he did not think that reporting them was a part of his duty. He had known cases where surgeons, recognising that operations might end fatally, had decided to give patients their only chance of living by performing such operations which had repeatedly been successful in the saving of life. He was of opinion that if inquests were held in all such cases in future medical men "would not undertake the responsibility of performing operations, and the odium attached to them." He had heard medical men say they would not operate in these desperate cases. "They had to consider their own reputation." The coroner said that personally he failed to see why the operation should not have taken place, "because there was a certain amount of publicity attached to it." If, therefore, it had of necessity to be performed in a poor house, in "a mean street," would the absence of publicity be a bar to an operation? Dr. F. W. Collinson, who was also called, said that in this desperate case they might have found a condition which would have led to the man being cured. He said he had operated on nine similar desperate cases in three years, and five patients were living to-day. "Whatever was said outside, doctors must, of course, do their best." The verdict was that the man had "died about three hours after a professional operation had been performed for obstruction of the bowels, and that such death was accelerated by the operation." One juryman held out against the latter portion of the verdict, believing it might frighten the public into not allowing their relatives to undergo operations, but, not converting the others to his opinion, he gave way to theirs. It is not clear that there was any evidence to show that the poor fellow's life was shortened, and the latter part of the verdict was speculative and does not seem to be justified. Be this as it may, such cases are very anxious ones. Where possible, of course, the consent of the patient or his nearest relations would be obtained; but if this cannot be done then the surgeon will use his own judgment, and act according to it, without regard to what the consequences to himself may turn out to be.

Sept. 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Closing of the Corporation Milk Depôt, Glasgow.

THE end of an interesting experiment has been seen in Glasgow by the determination of the corporation to close the milk depôt established by it some years ago to supply the infants of the poorer districts of the city with milk specially prepared and suitably diluted according to the age of each child. At the time the depôt was instituted there was difficulty in getting into touch with the mothers of newly-born infants, but since the Notification of Births Act and the establishment of consultations for infants, together with the appointment of a nurse and the aid which the Infant Health Visitors' Association renders, a more satisfactory means than the milk depôt of dealing with infant mortality has been provided. During the early days of the depôt, when the milk was issued without restrictions, the daily sales reached an average of 700. When approval of the family medical attendant or of the medical officer was introduced a shrinkage took place until the establishment of the Lord Provost's fund for the relief of distress, when the daily sales again reached between 600 and 700. But on the

cessation of this the daily numbers again fell, and now average about 300. The number of infants on depôt milk at present is thus only about 1·3 per cent. of the total number under one year of age. Another point which was urged for closing the depôt was that it was not the most neglected children of the city who were getting the depôt milk, but the children of mothers who, even if there had been no such supply of milk, would have fed their children comparatively well. Further, by comparisons of children's weights, there was no evidence that prepared milk possessed special advantages as a food. And, finally, it has been found that the cost of the preparation of milk at the depôt largely exceeds the sum realised on distribution. After a lengthy debate on the subject the corporation, by 38 votes to 22, decided to close the depôt. It was suggested that it would be advisable to inquire of milk purveyors whether any of them are prepared to place on sale clean bottled milk produced under conditions which would satisfy the health committee, and in this way imitate the certified milk supply of some cities in America.

Medical Inspection of Schools in Aberdeen.

Dr. G. Rose, medical officer to Aberdeen School Board, in his first report to the school board, gives an outline of the scheme adopted, and with regard to conditions and diseases due to neglect states that "the percentage of diseases of vermin of the head and body may well disturb the self-complacency of the community, as the figures show a state of matters not creditable to the city nor, indeed, to civilisation. ..... While the board can, and would, clean the children such action would be of little use unless the families and homes were also made clean. Negotiations are being carried on with the sanitary authorities to effect this, and it is hoped that they may come to a successful issue." The report states that diseases of the nose and throat are prevalent and a serious amount of decay of teeth. Rickets is more common in Aberdeen than elsewhere. Facts ascertained as to height and weight coincide with other towns where the same defects appear and where the same problem as to remedy presents itself.

Aberdeen Parish Council Medical Officership.

I understand that no applications have as yet been received for the post of visiting medical officer to the Oldmill Poorhouse. It will be remembered that the post was advertised first at a salary of £75 annually. The local branch of the British Medical Association, however, considered that anything under £150 would be inadequate remuneration for the time required, and advised its members not to apply for the post. The parish council then agreed to offer the sum of £105 annually, but the Association decided to stick by the original resolution and stipulate on a minimum salary of £150. The outcome of the situation is being awaited with much interest by the citizens generally.

Forfarshire Joint Committee and the Use of Paraffin for Pediculosis.

The Forfarshire Joint Committee on the Medical Inspection of School Children met at Forfar on Sept. 19th in order to consider the first annual report of Dr. N. J. Sinclair, the medical inspector. A member of the committee drew attention to the suggestion of Dr. Sinclair regarding the use of paraffin for pediculosis. While he understood that the parents were warned against the danger of fire, mistakes were bound to arise, and any suggestion of the kind was far too dangerous. In a case of fire the consequences would be simply horrible, and it might mean that a girl would be burned to death. Dr. Sinclair pointed out, in reply, that it was necessary to help the people in every way, so that they could have no objections to the materials on the ground of cost. It was agreed to delay considering the matter until next meeting.

Sept. 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Philanthropic Reform Association.

IN an address to the Philanthropic Reform Association last week the Earl of Meath, dealing with the question of Poor-law reform, urged that the essential changes might be summed up in the word "classification." This meant that the aged, the lunatics, the invalids, the able-bodied, were to be kept in separate buildings, with separate and diverse staffs, and under different treatment. If classification was to be carried out the unions must for some purposes, at any rate, be amalgamated into larger districts in order that the old workhouses in each union might be used for special purposes, one becoming the hospital for the whole of the larger district, another the almshouse for aged people, and so on, thus avoiding the necessity for new buildings on a large scale. The rates also which were levied for the support and maintenance of these institutions must be levied over the larger area, and for these purposes there must be an end of union rating. The simplest and most radical way of effecting the change would be to give to the county councils the whole of the duties now discharged by the Poor-law guardians. The committee of this association had signified its agreement with this proposal, with certain reservations. As regards the able-bodied poor, his lordship thought that they should be withdrawn from the care of local authorities and entrusted to the State, which already dealt with the unemployed by means of Labour Exchanges. Resolutions were passed at the meeting suggesting the holding of a conference on Poor-law reform between the Poor-law guardians and others interested in the matter, and calling on the Government to give power to boards of guardians to maintain sane epileptics in suitable colonies. It was stated that the Countess of Meath had offered to equip a home for epileptics, but the Local Government Board had pointed out that it was not within the power of guardians to contribute to its maintenance.

Criticism of a National Medical Service.

Since the issue some weeks ago by the British and Irish Medical Associations of a joint circular in favour of a national medical service for Ireland some letters have appeared in the daily papers in opposition to the scheme. These letters are mostly unsigned and do not tend to discredit the belief that the majority of the profession is in favour of a national medical service. The main point made in them is that by the establishment of a State service there will necessarily be some delegation from the powers of local authorities, and it is suggested that underlying the simple suggestion of a national service is some deep-lying political motive. A curious point put forward in criticism of a national service is that it may attract professional men from parts of the kingdom other than Ireland, and it has actually been urged that competition should be limited to Irishmen.

Poor-law Medical Officers and Consultants.

A point which frequently causes friction between Poor-law medical officers and boards of guardians is the attempt of guardians to control the choice of medical officers in a consultant. It often happens that guardians desire their medical officers to employ a certain medical gentleman in all cases where they require extra medical assistance. An instance of this occurred recently in Killarney, and the Local Government Board had to point out that any such direction by the guardians was *ultra vires*. In urgent cases the workhouse medical officer was bound to call to his assistance the nearest available duly qualified medical practitioner, and no resolution of the guardians could relieve him of this responsibility. On the other hand, a dispensary medical officer requiring extra professional assistance was authorised by the regulations to obtain the services of any practitioner he might wish to employ. It is unfortunate that a like discretion is not permitted to the workhouse medical officer, as obviously the nearest medical man is not always the most helpful in every class of case.

Royal Victoria Hospital, Belfast.

It is most satisfactory to be able to announce that already the sum of money promised for the erection of a new wing at the Royal Victoria Hospital, Belfast, as a memorial to the late King, amounts to over £10,500. At a meeting of the board of management of the Royal Victoria Hospital held on Sept. 21st, it was resolved unanimously that subscribers to the King Edward VII. memorial fund, to be devoted to the benefit of the hospital, shall be treated in regard to privileges in all respects as if their donations had been paid direct to the hospital—that is, as regards endowing and naming beds in that institution, and also as regards naming or nominating life-governors of the hospital.

Insanitary Condition of Portadown.

At the mid-monthly meeting of the Portadown town council held on Sept. 20th the medical officer of health, Mr. J. L. Rowlett, in answer to a question, said there were at least 100 working-class houses in Portadown in an insanitary state, and that a great number of them ought to be declared

insanitary areas that cannot be made sanitary owing to the want of air-space. A special meeting of the council is to be held to consider this extraordinary situation.

Clones Water-supply.

Clones, one of the leading towns in the North of Ireland, is threatened with a water famine owing to the cutting off of the water-supply for the past ten days. It would appear that owing to complaints the urban council decided to have the water-main pipe thoroughly scraped, and to do this ten days ago the water-supply was cut off. But when the work was entered upon the scraping apparatus suddenly stopped at some unknown point in the pipes, and all efforts to discover the machine have failed up to Sept. 24th. Now the only supply available for Clones is from a few pumps scattered here and there over the town, a very doubtful service in most cases. Great anxiety prevails in Clones, and it is hoped that the town surveyor will soon get matters right again.

The Belfast Hospital for Sick Children.

On Sept. 23rd Dr. W. McCready was elected ophthalmic surgeon to this institution, in place of the late Dr. Joseph Nelson.

Sept. 27th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Congress Season.

MANY congresses are being held in various places at this time of year. The Congress of Obstetrics and Gynæcology, which met at Toulouse from Sept. 22nd to 27th, unfortunately coincided as regards the date with the international congress on the same subject held in St. Petersburg. The date of the last-mentioned congress was several times altered on account of the political troubles in Russia, and there was even some uncertainty as to whether it would take place this year on account of the presence of cholera. These simultaneous meetings are mutually injurious, and for the purpose of avoiding these mishaps a permanent committee of the International Medical Congresses was formed last year at Budapest—a step which was heartily commended by the British Section of the International Association of the Medical Press. Although the two congresses on obstetrics were concurrent, as already mentioned, the one held at Toulouse was very successful, and among the various papers that were read, one by M. Fieux on the uncontrollable vomiting of pregnancy attracted much attention. In addition to the meetings announced in your Diary of Congresses I may mention that the Eleventh French Congress of Medicine will meet in Paris from Oct. 13th to 15th. Professor Landouzy will preside, and three discourses are announced in the official programme, one on bradycardia (delivered by M. Vaquez, M. Esmein, and M. Gallavardin), one on the treatment of symptomatic epilepsy (delivered by M. Souques, M. Bosc, and M. Vires), and one on the pathological relations of the liver and spleen (delivered by M. Gilbert, M. Lereboullet, and M. Roch); there are also on the programme four subjects for discussion by the meeting—namely, the ill-effects occasioned by serum treatment, acute cerebro-spinal meningitis, the tuberculin treatment, and the diseases of the pancreas. The Congress of the French Surgical Association will take place at the Faculty of Medicine on Oct. 3rd, Dr. Delagenière of Le Mans being in the chair. The French Association of Urology will meet on Oct. 6th; Professor F. Guyon will preside and the subject on the official programme is Urethral Stricture not dependent on Gonorrhœa or Mechanical Injury. The Second International Conference for the Study of Cancer will be held in Paris from Oct. 1st to 5th; Professor Bouchard is the president of the French committee.

The "Office National" of the French Universities and Schools.

Under the name of the *Office National* of the French Universities and Schools, an organisation has been formed in Paris for the purpose of publishing in foreign countries full information with respect to the educational advantages which France offers to foreign students. The president of the managing committee is M. Paul Deschanel, a deputy and a member of the French Academy. The director of the Office is Dr. Raoul Blondel, director of the information bureau of the University of Paris, and for the present its work is carried on at the Sorbonne.

Intraspinal Injections of Mercurial Salts.

M. A. Lévy, M. Bing, and M. Georges Lévy have recently published in the *Annales des Maladies Vénériennes* a memoir on the intraspinal injection of mercurial salts, a new therapeutic procedure which they have employed principally in the treatment of syphilitic diseases of the nervous system, making use either of ordinary mercurial compounds or of colloidal mercury. They recommended subarachnoid administration by means of a puncture made between the second lumbar vertebra and the sacrum. The patient ought to keep his bed for the ensuing 48 hours, because pain and loss of power in the lower limbs were frequently observed. Benzoate of mercury in doses of 1 centigramme was the best salt for the purpose, the biniodide being more painful in its action. Mercury was never found in the urine. The conditions in which the most encouraging results were obtained were specific spinal meningitis, spinal paralysis, and cases of acute syphilitic myelitis. The treatment must be applied in an early stage. In tabes success was, perhaps, possible when energetic treatment was adopted at the outset, but advanced forms of the disease were not benefited. The indications for treatment were, therefore, somewhat limited, and although this method was very interesting from the experimental point of view it was not at present likely to obtain recognition in ordinary practice.

Fraudulent Claim for Compensation by a Workman.

A man employed at a restaurant has recently been sentenced by the tribunal of the Seine to three months' imprisonment and a fine of 25 francs. His offence was that his forearm having been scalded in his occupation of dish-washing he kept the sores open for several months in order that he might draw the sum allowed him by the insurance company as an injured workman. He produced two certificates by medical men who had examined the sores, and the court in giving judgment censured these practitioners for granting certificates of this kind merely for the sake of the fees.

Medical Men and the Speed of Motor cars.

A medical man driving at full speed in a motor-car to visit a patient was arrested by the police for having exceeded the speed limit. The court acquitted him on the ground that a medical man hastening to a patient in danger of death might be considered as answering the legal definition of *force majeure*.

Sept. 27th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

"The Hygiene of Journalism."

UNDER this title the Italian press is discussing its own responsibility for the appalling tale of homicides, suicides, thefts, embezzlements, and sins against society which give their country a sinister priority among its continental sisters. Are the journals—daily, weekly, and illustrated—performing the wholesome, the educative, function they profess to discharge in giving such detailed publicity to crime; in making so prominent the assassin, the self-murderer, the "borsaiuolo abilissimo" (the accomplished pickpocket), the "elegantissima truffatrice" (fashionable lady swindler), the peculating prefect, and the absconding banker, whose feats they record with a fulness and a dramatic force that convert the protagonist into a celebrity, if not a hero, and earn for him a sneaking admiration, nay, a positive fellow-feeling, on the part of many a reader? Are they not feeding and fostering that imitative instinct which man, more or less, shares with the anthropoid ape, by subjecting it to the contagion of examples often romantic, picturesque, and generally seductive? To these questions one of the ablest of Italian journals, bearing an honourable record in the national "Risorgimento," the Florentine *Nazione*, gives a reply emphatically in the affirmative, and appeals to its contemporaries, many of them as authoritative as itself, to give less publicity to the sinister and more to the honourable and exemplary incidents that come within their cognisance. The appeal is as well-timed as it is well-inspired, and will, it is hoped, evoke a response conducive to "that sacred and sound contagion" which the well-ordered

citizen can exert on his neighbour the more his conduct is put in evidence. The "liberty of the press," says the *Nazione*, "ought not to be the liberty of infection," and journalism will find its account, even financially, in letting the normal and health-giving developments of society take precedence of the irregular and degrading. It will have no lack of material, when even the misanthrope Heine could sing—

"Und wie viel ist dir geblieben,
Und wie schön ist noch die Welt,
Und, mein Herz, was dir gefällt
Alles, alles, darfst du lieben!"

Pornography.

To pursue somewhat the same train of thought, which events in Italy make a topical one, once and again I signalise the efforts of the Government to restrict, and finally to suppress, the sale of lascivious publications, illustrated or not illustrated, "plain or coloured," the diffusion of which has now attained (not in Italy only) the proportions of an "immoral epidemic." It is indeed a disheartening spectacle for all well-wishers of Italy, particularly of "the Italy that is to be," to see children of tender years and of both sexes gloating over the so-called "comic journals" exposed to view and to sale at every kiosk or street corner, often indeed in the shop windows of booksellers posing as "respectable." These prints, under the pseudonym of "comic," are really meretricious in the grossest sense, and are the *causa causans* of that physical and moral deterioration which always ensues on premature indulgence in the marital privilege, leading up to (or rather down to) the homosexualism and Sapphism which are known to be rife in Southern Italy. The Italian Premier, Signor Luzzatti, as already recorded in THE LANCET (July 16th), has taken vigorous measures against this nefarious "literature," and within three months of the issue of his circular for its confiscation and prohibition has achieved gratifying and reassuring results. In terms of the circular in question, the police, mainly in Turin, Genoa, Venice, Florence, Rome, Naples, and Palermo, have proceeded to the arrest and "denunciation" of more than 100 "traffickers in obscenity," while impounding no fewer than 32,000 postcards, 6500 photographs, 2200 books and "pamphlets," to say nothing of "objects," kinematograph films, dolls, cigarette cases, hand-mirrors, and so forth, all pandering to the most depraved animalism. The individuals arrested have been mainly itinerant vendors of postcards and illustrated journals, so-called "laqueys de place," and immoral touts, and the publications have been largely stopped at the custom-houses, the railway termini, and the landing-quays. The royal procurators and judges of tribunals have allowed but few of the prisoners brought before them to escape their penalty, and it is one very hopeful symptom that the public are coöperating with the prefects in giving the police such information as may facilitate the enforcement of the law. Almost daily (I am assured) reports are forwarded to the Ministry of the Interior, over which the Premier presides, to stimulate and strengthen the officers of the crown in their beneficent crusade—it being the firm determination of His Excellency Signor Luzzatti "che la campagna moralizzatrice continui con oculata ma tenace energia" (that the campaign in promotion of morality shall be prosecuted with vigilant but unrelaxing energy).

Sept. 22nd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Professional Secrecy and the Law Courts.

A DECISION of the highest Court of Justice in this country, which finally settled a long dispute, has been much commented upon, for it shows that a patient can no longer rely on his medical attendant's silence with respect to professional matters. The law passed in 1852 has hitherto always allowed a practitioner to keep to himself what he knows as to the ailments of his patients, even in a court of law; but in a divorce suit heard recently in one of our largest cities the medical adviser of the husband was called as a witness and the judge ordered him to disclose the nature of the man's illness, which the wife alleged was contagious. The practitioner on being informed that a certain paragraph of the common law orders such a disclosure to be made to the judge and to nobody else, gave evidence accordingly, and as the wife's assumption was right the action was decided in her favour. The husband in appealing against this decision alleged that the first judge had erred in ordering the medical man to disclose what he knew and thereby to violate the law, but the appeal was dismissed, and in the third and last instance the husband's claim was again dismissed. It therefore appears that according to the law of this country the confidential relations between practitioner and patient are not inviolable. The law, in fact, declares that a medical practitioner, a midwife, or an accoucheur who discloses the secrets of a patient to anyone other than an officially constituted authority shall for the first offence be suspended from practice for three months, the next time he shall be suspended for one year, and the third time altogether. A new Bill which is now under consideration is less considerate for the general public and no doubt it will call forth very vehement protests. It provides that breach of professional secrecy may be excused if it has been the means of preventing anything to the public detriment or has protected private interests. It binds medical men, lawyers, and apothecaries, as well as their subordinates, to keep secret all knowledge which they obtain through their occupation, and the same rule applies to students of medicine who may get such knowledge in the course of their studies. It punishes such offence with imprisonment for a period varying from two weeks to two years, or with a fine of 2000 kronen (£80). Proceedings will be taken only if the person who considers himself aggrieved makes application to that effect. The above-mentioned decision, which is in harmony with a few other similar judgments given lately in this country, has been discussed in the various medical councils, and to the credit of the medical profession all these representative bodies were unanimous in declaring such an interpretation of the law to be unacceptable to the profession. The members of the local medical divisions were urged to refuse all disclosures of such a kind, even under the threat of punishment, professional secrecy being one of the most important obligations of a practitioner.

A Medical Insurance Company.

In the estimation of insurance companies medical practitioners occupy a disadvantageous position which necessitates the payment of increased premiums on their policies. This exceptional treatment has for a long time been a subject of controversy, and as the companies show no sign of giving way a group of medical men have founded a medical insurance company whose chief object is to insure their professional brethren against accidents. The premiums paid hitherto by medical men, even to the company offering the most liberal terms, are 40 per cent. higher than those required by the new company, which has been named "Kosmos." The shares of the new undertaking were offered to medical men only, and all of them very soon found buyers. At present it is intended to limit the business strictly to medical insurance. As actions for malpractice are at present increasing in Austria at an alarming rate this branch of insurance will also be taken up by the new company.

The Health of the Working Classes in Vienna.

The Krankencassa for Vienna is publishing monthly statistical reports showing the general state of health of its members, and as these reports are very carefully made, their value can hardly be overestimated. The number of the members who belong to the Krankencassa is 310,000, all being of full working age, between 18 and 60 years, so that a very considerable proportion of the wage-earning population is under constant scientific observation. A total of 35,000 females, married and unmarried, belong to the Krankencassa, being 11 per cent. of the members, whilst the aggregate of the members is 16 per cent. of the entire population of Vienna, or 30 per cent. of the population between the ages of 18 and 60 years. During last July 8631 members were incapacitated for work by reason of illness. More than 10 per cent. of that number (870) suffered from tuberculosis of the respiratory organs, whilst other diseases of these organs were observed in 750 instances. There were 27 cases of pneumonia amongst them, all the patients being ironworkers. 369 patients suffered from tonsillitis with high pyrexia, and 143 were laid up with influenza. Diseases of the circulation were reported in 320 cases, disturbances of

the alimentary canal in 768 persons, and rheumatic attacks in 694 cases. Among the latter, tonsillitis had existed in 120 cases between six days and 14 weeks previously. In 1799 instances, accidents had caused inability to work which had continued for more than three days, for only such cases were placed on the sick-list. The total number of deaths was 265, being 3 per cent. of the patients, or less than 0·75 per 1000 of all members. Tuberculosis claimed 89 victims, being 30 per cent. of all the deaths in this month, only 18 persons dying from other diseases of the respiratory organs in that time. 59 patients succumbed to heart disease and 17 to neoplasmata. Six accidents proved fatal, whilst 15 persons committed suicide, 12 of them taking their own lives in consequence of prolonged illness caused by incurable disease.

Sept. 26th.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. G. P. Van Trooyen has been recognised as *privat-docent* of Surgery.—*Berlin:* Dr. Georg Gaffky, Director of the Institute of Infectious Diseases, has been appointed Honorary Professor.—*Bologna:* Dr. Goffredo Sorrentino has been recognised as *privat-docent* of Dermatology, and Dr. Fabio Rivalta as *privat-docent* of Internal Pathology.—*Bonn:* Dr. Friedrich Fröhlich, *privat-docent* of Physiology, has been granted the title of Professor.—*Budapest:* Dr. Markus Pauntz has been recognised as *privat-docent* of Otology and Laryngology.—*Catania:* Dr. Domenico Mirto of Sienna, has been appointed to the Chair of Medicine.—*Clausenburg:* Dr. Ludwig Góth has been recognised as *privat-docent* of Gynæcology.—*Florence:* Dr. Pietro Bastianelli has been recognised as *privat-docent* of Operative Medicine, and Dr. Francesco Motolese as *privat-docent* of Ophthalmology.—*Geneva:* Dr. G. B. Zanda, of Messina, has been recognised as *privat-docent* of Materia Medica and Experimental Pharmacology, and Dr. Giovanni Galli as *privat-docent* of Internal Pathology.—*Halle:* Dr. Berthold Pfeiffer, *privat-docent* of Neurology, Dr. Arthur Menzer, *privat-docent* of Medicine, and Dr. Hildebrandt, *privat-docent* of Pharmacology, have been granted the title of Professor.—*Heidelberg:* Dr. Erich Grafe has been recognised as *privat-docent* of Medicine.—*Kazan:* Dr. D. V. Polumordrinoff has been promoted to the chair of Physiology.—*Modena:* Dr. Giuseppe Ovis, extraordinary professor of ophthalmology, has been promoted to be Ordinary Professor.—*Montreal:* Dr. J. C. Simpson has been appointed to the chair of Histology and Embryology.—*Munich:* Dr. W. Gilbert has been recognised as *privat-docent* of Ophthalmology.—*Naples:* Dr. Antonio Lombardi has been recognised as *privat-docent* of Therapeutics.—*Palermo:* Dr. Ernesto Paltacca has been recognised as *privat-docent* of Ophthalmology.—*Philadelphia (University of Pennsylvania):* Dr. David L. Edsall, professor of therapeutics, has been appointed to the chair of Medicine in succession to Dr. James Tyson, resigned. Dr. Paul A. Lewis has been appointed Adjunct Professor of Pathological Anatomy.—*Pittsburg:* Dr. Oscar Klotz of McGill University has been appointed to the chair of Pathological Anatomy.—*Rome:* Dr. Agenore Zeri, Extraordinary Professor of Medical Semeiology, has been promoted to be Ordinary Professor. Dr. Filippo Caccia has been recognised as *privat-docent* of Surgery, Dr. Tullio Luzzatti as *privat-docent* of Pædiatry, and Dr. Mario Fontana and Dr. Mario Serena as *privat-docenten* of Physical Therapeutics.—*Sassari:* Dr. Andrea Conti of Rome has been recognised as *privat-docent* of Internal Pathology.—*Seville:* Dr. Juan Bantista Teset has been appointed Professor of Forensic Medicine and Toxicology.—*Sienna:* Dr. Sante Solieri has been recoginsed as *privat-docent* of Surgery and Operative Medicine.—*St. Louis (Washington University).*—Dr. Georg Dock of Tulane University has been appointed Professor of Medicine; Dr. Joseph Erlanger, Professor of Physiology; Dr. Eugene L Opie, Professor of Pathological Anatomy; and Dr. John Howland, Professor of Pædiatry.—*St. Petersburg (Military Medical Academy):* Dr. V. A. Levasheff has been promoted to the chair of Hygiene and Police Sanitation. Dr. F V Verbitski has been recognised as *privat-docent* of Medicine.—*Sydney:* Dr. A. E. Mills has been appointed Lecturer on Medicine, and Dr. R. H. Todd Lecturer on Forensic Medicine.—*Vienna:* Dr. Viktor Widakowich has been recognised as *privat-docent* of Embryology.—*Würzburg:* The title of Professor has been granted to Dr. Karl Wessely, *privat-docent* of Ophthalmology.—*Zürich:* Dr. Karl Henschen has been recognised as *privat-docent* of Surgery.

THE annual dinner of the London School of Tropical Medicine will be held on Friday, Oct. 14th, at the Hotel Savoy, Mr. James Cantlie in the chair.

THE Public Inaugural Lecture at King's College, London, will be delivered on Oct. 5th by Professor David Waterston. The chair will be taken by Sir Alfred Keogh.

IN the obituary notice of Dr. T. E. Smyth of Tavistock, Devon, published in our issue of June 25th, 1910 (p. 1793), we inadvertently referred to "the late" Dr. Swale. Dr. Harold Swale is employed by the Sena Sugar Factory, Limited, Villa Fontes, Mozambique, and we tender him our apologies for implying that he was dead.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. Calhoun, professor of ophthalmology in Atlanta College of Physicians and Surgeons.—Dr. H. Kanitz, *privat-docent* of dermatology in Clausenburg.—Dr. Sigmund Mayer, professor of microscopic anatomy in the German University of Prague, at the age of 67 years. He was a pupil of Helmholtz and Brücke, and assistant to Professor E. Hering in Vienna, whom he followed to Prague. He was a voluminous writer on physiological and microscopical topics, and was highly esteemed in social circles in Prague.

THE WOMEN'S IMPERIAL HEALTH ASSOCIATION.—Under the auspices of this association two new health caravans are immediately to be sent on tour, one through the eastern counties and the other in the parks of the metropolis. The London County Council has given permission for the lectures in the parks to be illustrated by the kinematograph, and an invention for the use of this apparatus during daylight will be used for the first time. The "Aurora," the first caravan of the association, which was sent out on August 20th, has visited 19 towns and villages, and an evidence of the success of this first campaign is the fact that after the visit of the van to a town or village a much larger number of open windows could be counted than before the visit.

DONATIONS AND BEQUESTS.—The executors of the will of the late Louisa Sophia Lady Goldsmid have made a further distribution of £20,210, representing part of her residuary estate, and among the charities which have been selected for participation in this sum are: London Fever Hospital, Liverpool-road, £500; University College Hospital, £500; Friedenheim Hospital (Home of Peace for the Dying), Swiss Cottage, £1000; St. Luke's Home (Home for the Dying Poor), Pembridge-square, £500; Brompton Hospital for Consumption (for boarding-out scheme), £1000; Convalescent Homes Association (to form the nucleus of a fund in perpetuity, the interest on which is to be given from time to time in aid of needy convalescent homes), £1000; Victoria Home for Invalid Children, Margate, £750; Banstead Surgical Home for Boys, Banstead, £750; Convalescent Home for Poor Children, St. Leonards, £500; Mary Wardell Convalescent Home for Scarlet Fever, Stanmore, £500; Home for Invalid Gentlewomen, St. Leonards, £500; and Children's Home Hospital, Barnet, £500. Among the Jewish charities benefited are the following: Home and House of Rest and Convalescence, Broadstairs, £800; Jewish Convalescent Home and Sanatorium for Consumption, Hove, £300; and Baroness de Hirsch Convalescent Home, Hampstead, £300.—Among other large charitable bequests the late Mr. R. G. Vivian of Swansea and London has bequeathed £1500 for a Glynn Vivian bed at the Swansea Hospital, conditional upon the governors undertaking to use the legacy for the colliers, miners, or metal workers of Vivian and Sons, or men connected with the Miners' Mission; £1000 towards the endowment of the hospital for the blind founded by him recently; £500 to St. George's Hospital, London; and £50 each to the National Hospital for the Paralysed and Epileptic, the Swansea Institution for the Blind, and the

Swansea Institution for the Deaf and Dumb.—Mr. William Crawshay of Newnham, Gloucester, who died on July 11th, left £3000 to the Gloucester Infirmary.—Lady Mond has forwarded £479 17*s.* 3*d.* to the Infants Hospital, Vincent-square, Westminster, as part proceeds of the matinée recently given at His Majesty's Theatre in aid of the Infants Hospital and the Royal Waterloo Hospital.

SECOND INTERNATIONAL CONGRESS OF ALIMENTARY HYGIENE.—This Congress will meet in Brussels from Oct. 4th to 8th. On Tuesday, Oct. 4th, a lantern lecture by Professor Dastre on "The Ultra-violet Rays and their Application to Alimentary Hygiene" will be given; on Wednesday a lecture by Professor Paterno on "The Chemical Sciences"; on Thursday a lecture by M. Bordet, director of the Pasteur Institute, Brussels, on "Hygiene and Bacteriology." Members and Associates (subscription 20 francs and 10 francs respectively) are admitted free to the Universal Exhibition during the time of the Congress. Special railway facilities have been arranged. Further information may be obtained from the honorary secretary, Mr. Cecil H. Cribb, 136, Shaftesbury-avenue, London, W.

THE HOUSING AND TOWN PLANNING ACT, 1909.—We have before us the first series of procedure regulations issued by the Local Government Board of Scotland for the guidance of local councils applying for authority to prepare or adopt a town planning scheme within the Board's jurisdiction. The regulations are those which might be expected relating to notices to be given to other local authorities interested and to information required by the Board. The elasticity of the Act and the discretionary powers intentionally assigned to those making use of it are exemplified in Article XI. of the regulations, which promises permission to depart from them where the Board is satisfied that there is reasonable cause for so doing. Freedom of this kind will probably be appreciated in rural districts, where the Act is likely to be employed usefully but on a small scale to meet special circumstances.

THE MIDDLESEX HOSPITAL.—We have received a letter from Prince Francis of Teck, in which he informs us that he has now obtained the £20,000 which he asked for to enable him to remove the debt from the Middlesex Hospital, an anonymous friend having just handed him a cheque for £231. In expressing the deep sense of gratitude which he feels towards all those who have so loyally responded to his appeal, he says that rich and poor alike have contributed to the success of his effort, the sums received ranging from 1000 guineas to 3*d.* But the task is not yet finished, for the debt of £20,000 represented the accumulated deficits between income and expenditure for three years, and it is obvious that until a steady and permanent addition of £7000 per annum is made to the hospital's income its financial position is not secure. "It is my ambition," says Prince Francis of Teck, "to substitute, for a hand-to-mouth administration, one which will provide the governors with an income sufficient to meet the normal expenses of the year."

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on Sept. 16th. There were present: Dr. de Havilland Hall (in the chair), Mr. J. Brindley James, Dr. M G. Biggs, Dr. J. W. Hunt, Dr. F. C. Martley, Dr. Frederick S. Palmer, Mr. Frederick Wallace, Mr. H. P. Symonds (Oxford), Dr. H. A. Sansom, Mr. F. S. Edwards, Mr. J. F. Colyer, Dr. F. J. Allan, Dr. St. Clair B. Shadwell, Dr. M. Greenwood, and Dr. J. B. Ball. The accounts presented showed that the business was satisfactorily progressing. As usual during the summer months, the sickness experience has been well under the amount expected and provided for in the tables of contribution, and a considerable sum has thus been added to the large reserves of the society. These have grown steadily from the time when the society first started its operations and now amount to over £240,000. There is no fear that the liberal conditions offered by the society to its members will have to be curtailed for many years to come. Prospectuses and all information can be obtained on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

Urgent Surgery. By Félix Lejars, Professeur Agrégé à la Faculté de Médecine de Paris. Translated from the Sixth French Edition by William S. Dickie, F.R.C.S. Vol. II. The Genito-Urinary Organs, the Rectum and Anus, the Strangulated Hernias, the Extremities. Price 25*s.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ALFORD, E. F. R., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Woodbridge District of the county of Suffolk.

APPERLY, R. E., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Anæsthetist to the Middlesex Hospital.

BERRY, GEORGE A., M.B., C.M. Edin., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Sheriffdom of the Lothians and Peebles, with a view to his being employed in ophthalmic cases which may arise in the Sheriffdom.

BUCK, HOWARD, M.B., Ch.B. Vict., F.R.C.S. Eng., has been appointed Assistant Surgical Officer to the Manchester Royal Infirmary.

COLE, SAMUEL JOHN, L.R.C.P. Lond., M.R.C.S. Eng., has been elected a Fellow of the Royal Institute of Public Health.

DODDS, THOMAS GEORGE BOSWALL, M.D., Ch.B. Edin., has been appointed *pro tem* Medical Officer and Public Vaccinator for the Northern District of the Cirencester (Gloucestershire) Union.

EMRYS-ROBERTS, E., M.B., Ch.B. Vict., M.D. Liverp., has been appointed Professor of Pathology at University College, Cardiff, and Pathologist to the Cardiff Infirmary.

HICHENS, FRANK, M.D., B.S. Lond., M.R.C.S., L.S.A., D.P.H. Eng., has been reappointed Medical Officer of Health for the Redruth (Cornwall) Urban District.

HUNTER, MITCHELL, M.D. Miami Med. Coll., L.S.A., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for the City and County of Londonderry.

MCBEATH, WILLIAM, M.D., M.Ch. R.U.I., D.P.H. Camb., has been appointed Medical Officer for the Kingsteignton District by the Newton Abbot (Devon) Board of Guardians.

MAPLETON, HENRY BANBURY, M.D., C.M. Edin., D.P.H. Lond., has been reappointed Medical Officer of Health for the Newton Abbot (Devon) Urban District.

O'KANE, MICHAEL, M.B., L.S.A. Lond., M.R.C.S., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for the City and County of Londonderry.

QUIRK, E. J. J., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at Charing Cross Hospital.

RABY, LEONARD, M.D. Durh., M.R.C.S., L.S.A., has been reappointed Medical Officer for the Third District by the Devizes (Wilts) Board of Guardians.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and lodging.

BATH, ROYAL MINERAL WATER HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with lodging, board, and washing.

BEDFORD COUNTY HOSPITAL.—House Physician. Salary £60 per annum, with apartments, board, and washing.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Two House Surgeons for six months. Salary at rate of £75 per annum, with board and residence.

BRIGHTON AND HOVE HOSPITAL FOR WOMEN.—House Surgeon, unmarried, for six months. Salary £30 per annum, with apartments, board, &c.

CARDIFF INFIRMARY.—Honorary Ophthalmic Surgeon.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—Registrars and Clinical Assistants.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £75 per annum, with board and lodging. Also Surgeon-in-Charge of Branch Dispensary. Salary £80 per annum, with board and lodging.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £60 per annum, with board, apartments, and laundry.

COLCHESTER, BOROUGH EDUCATION COMMITTEE.—Assistant School Medical Officer (female). Salary £250 per annum.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence. Also House Physician. Salary £80 per annum, with board, residence, and washing.

DENBIGH, DENBIGHSHIRE INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, laundry, &c.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Second Medical Officer for six months. Salary at rate of £40 per annum, with luncheon and tea.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—House Surgeon. Salary £120 per annum, with board, apartments, and washing.

HALIFAX, ROYAL INFIRMARY.—Second and Third House Surgeons, unmarried. Salary £100 and £80 respectively, with residence, board, and washing.

HAMPSTEAD GENERAL HOSPITAL.—House Physician and House Surgeon for six months. Salary at rate of £70 per annum, with board and residence.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with rooms, board, and washing.

HELLINGLY, EAST SUSSEX COUNTY ASYLUM.—Assistant Medical Officer and Pathologist, unmarried. Salary £250 per annum, with board, lodging, washing, &c.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Fourth Anæsthetist. Salary £15 15s. per annum. Also House Surgeon, unmarried, for six months. Salary £30, with board, residence, &c.

HULL ROYAL INFIRMARY.—Senior House Surgeon, unmarried. Salary £150 per annum, with board and apartments.

JERSEY INFIRMARY AND DISPENSARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and attendance.

KETTERING AND DISTRICT GENERAL HOSPITAL.—Resident Medical Officer, unmarried.

KING EDWARD VII. SANATORIUM, Midhurst, Sussex.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and attendance.

LEEDS, HOSPITAL FOR WOMEN AND CHILDREN.—House Surgeon for six months. Salary at rate of £50 per annum, with board.

LONDON HOSPITAL, Whitechapel, E.—Two Surgical Registrars. Salary £100 per annum each.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MANCHESTER ROYAL INFIRMARY.—Surgical Registrar. Salary £70 per annum.

MANCHESTER WORKHOUSE INFIRMARY, Crumpsall.—Visiting Surgeon Salary £150 per annum.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Assistant House Physician for six months. Salary at rate of £20 per annum, with board and residence.

MORPETH, NORTHUMBERLAND COUNTY ASYLUM.—Junior Assistant Medical Officer (female). Salary £120, with board, apartments, laundry, and attendance.

NEWCASTLE, CO. WICKLOW, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION FOR IRELAND.—Junior Resident Medical Officer. Salary £75 per annum, with board and residence.

NEWCASTLE-UPON-TYNE CITY ASYLUM, Gosforth.—Junior Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, and laundry.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Honorary Dental Surgeon. Also House Physician and House Surgeon for six months. Salary in each case at rate of 50 guineas per annum, with board and residence.

RADNOR COUNTY COUNCIL.—County Medical Officer of Health and County School Medical Officer. Salary £300 per annum.

RAINHILL COUNTY ASYLUM, near Liverpool.—Assistant Medical Officer, unmarried Salary £150 per annum, with apartments, board, washing, &c.

READING, ROYAL BERKSHIRE HOSPITAL.—House Physician and Second House Surgeon, both for six months. Salary £30 and £60 per annum respectively, with board, lodging, and washing.

ROBERT BROWNING SETTLEMENT, Walworth, S.E.—Honorary Superintendent.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Resident House Surgeon, unmarried, for six months. Salary £100, with board, residence, and washing.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Commissions.

ST. MARYLEBONE ANTI-TUBERCULOSIS DISPENSARY.—Medical Officer. Salary £250 per annum.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £80 per annum.

SALFORD ROYAL HOSPITAL.—Honorary Assistant Surgeon.

SOUTHPORT INFIRMARY.—Resident Junior House and Visiting Surgeon, unmarried, for six months. Salary £70 per annum, with residence, board, and washing.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Senior and Junior House Surgeons. Salary £100 and £90 per annum respectively, with residence, board, and washing.

SUNDERLAND WORKHOUSE, Hylton-road.—Resident Assistant Medical Officer. Salary £120 per annum, with rations, apartments, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Act at Tighnabruaich, in the county of Argyll; at Painswick, in the county of Gloucester; and at Ryde (Isle of Wight), in the county of Hants.

Births, Marriages, and Deaths.

BIRTHS.

DANIEL.—On Sept. 21st, at 8, St. James's-avenue, West Ealing, the wife of Alfred W. Daniel, M.D. Cantab., of a son.

DAVIDSON.—On Sept. 26th, at Queen's-road, Coventry, the wife of Duncan Davidson, M.B., B.Ch. Oxon., of a daughter.

DOUTY.—On Thursday, Sept. 22nd, at The Manor House, Clifford Chambers, Gloucestershire, the wife of Edward H. Douty, of a son.

FALK.—On Sept. 23rd, at Dunedin, Chichester-road, Croydon, the wife of Captain H. Falk, I.M.S., of a son.

HODGES.—On Sept. 21st, at Cotelands, Buxton, the wife of Dr. A. D. P. Hodges (of Uganda), of a daughter.

KEELING.—On Sept. 24th, at Market Bosworth, the wife of Hugh Nevill Keeling, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

TAYLOR.—On Sept. 20th, at Tun Bridge, Liphook, the wife of J. J. Taylor, M.A., M.D., of a son.

WILLCOX.—On Sept. 18th, at Welbeck-street, W., the wife of W. H. Willcox, M.D., of a son.

MARRIAGES.

PURNELL—BEE.—On Sept. 19th, at St. Martin-in-the-Fields, London, Charles Arthur Purnell, M.B., to Nora Kathleen Jean, daughter of James Bee, Normanhurst, Lee, Kent.

ROOME—PETTER.—On Sept. 20th, at Bromley Parish Church, Alfred Martin Roome, M.R.C.S. Eng., L.R.C.P. Lond., to Charlotte Eleanor, youngest daughter of the late Arthur Petter and of Mrs. Petter, of St. Matthew's-gardens, St. Leonards-on-Sea.

WARD—MARGRAVE.—On Sept. 21st, 1910, at All Saints' Church, Llanelly, by the Rev. Watcyn Morgan, Vicar of the parish, assisted by the Rev. J. Popkin Morgan, uncle of the bride, Ernest Ward, M.D., M.A. Cambridge, F.R.C.S. Eng., third son of the late Sir John Ward of Leeds, to Nora, eldest daughter of Fred Margrave, Esq., of the Old Vicarage, Llanelly.

WILLIAMS—HENSHAW.—On Sept. 24th, at the Church of St. Michael and All Angels, Bedford Park, Cyril O. O. Williams, M.R.C.S., L.R.C.P., to Gertrude Mabel W. Henshaw, youngest daughter of William A. Henshaw, of Esmond-road, Bedford Park.

DEATHS.

CHURCHILL.—On Sept. 1st, at Swatow, China, from hydrophobia, John Aylward Churchill, M.R.C.S., L.R.C.P., aged 35 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"THE STERILISED TRAIN."

THE opening of the tourist season south of the Alps is within measurable distance, and the "Amministrazione delle Ferrovie di Stato" (writes an Italian correspondent) is laudably engaged in providing for the comfort of the passenger and also for his protection from risk to health. In both respects there has hitherto been much to be desired; but in the latter, with the cholera scare menacing the mainland and islands, the necessity for increased vigilance in the prevention of contagious or infective disease is, literally, a *prima cura*. To ensure the custom of the paying traveller who is also a paying guest, there must be rigorous exclusion of that other type of traveller and guest ("non-paying" in every sense!) which has hitherto found a place, particularly in first-class carriages—the microbe, to wit, as protean in its form as it is noxious in its effects. "The padded arm-chairs," according to a sub-alpine authority on hygiene, "are quite a preserve or hot-bed of animalcule life, abounding in bacteria, cocci, vibriones, spirochætæ, to mention a few varieties, whose contact with the passenger, prolonged for hours by day and night, is about as risky an experience as he can encounter." With the head resting on a cushion surcharged with these microbes (the previous "fare" having often imparted a contribution of his own), the unsuspecting passenger exposes himself to infection of every kind, resulting often enough (according to the medical authority above referred to) in "precoce calvizie" (premature baldness) from continued pressure against the said cushion, while courting, among other bacilli, that of tuberculosis or of diphtheria itself. The overheating of the train, the indisposition, not to say the positive resistance, of the continental, particularly the Teutonic, fellow-passenger to the admission of fresh air, maintains a temperature at which bacilli of every kind are at their maximum of infectivity. To this cause was attributed during the last winter and spring in Italy the increase of victims to influenza, many of whom traced their having contracted it to a six or seven hours' journey in a stifling atmosphere, itself a "blend" of all manner of infective agencies. "To travel under conditions hygienically sound, in a carriage 'batteriologicamente puro,' such is the *sine quâ non* of railway transit," says the authority already quoted, adding useful hints in other directions, one of them being the observance of punctuality, or the coincidence of departure and arrival with the figures of the time-table, for which he humorously suggests "un orario sterilizzato" (a sterilised Bradshaw or A.B.C.). But even this unpunctuality of trains, involving prolonged detention on draughty platforms or in stuffy waiting-rooms, is of secondary consideration to the hygienic purity of the rolling-stock. So, to sum up, there is little or no time to lose on the part of the Italian lines, now under State control, in originating and running "il treno sterilizzato"—especially when the great International Exhibitions to be held in Turin and in Rome next year are likely to attract a greater number of visitors from abroad than Italy has yet had to convey and to cater for.

THE VALUE OF BOOK-DEBTS.

To the Editor of THE LANCET.

SIR,—In buying a practice and taking over the book debts, what amount in the £ is it customary to pay for the latter?

I am, Sir, yours faithfully,

Sept. 26th, 1910. GENTIAN.

*** It is impossible to give much idea from these data. As a rule it is not advisable or customary to buy book debts, but if it is done the value may be anything from 2*s.* 6*d.* to 17*s.* 6*d.* in the £. A recent debt in a good-class practice would be worth the higher figure, but an old account from a poor patient would be valueless. "Gentian" should have the debts properly valued by a medical accountant used to such business.—ED. L.

HEALTH AND SANITATION IN SIERRA LEONE.

IN his report to the Colonial Office on the Blue-book of Sierra Leone for the year 1909, just issued as a Parliamentary paper, Mr. G. B. Haddon Smith, C.M.G., deals at some length with questions of health and sanitation in both the Colony and Protectorate. The estimated area of the former is 4000, and of the latter 27,000, square miles. The territory is bounded on the north and north-east by French Guinea and on the south-east by the negro republic of Liberia, whilst on the west the Atlantic Ocean forms the boundary. The population of the colony is estimated at 76,572; that of the Protectorate at 1,146,000. Freetown, the capital of the colony, had an estimated population on Dec. 31st, 1909, of 39,531, and the death-rate during the year was 19 per 1000 and the birth-rate 13 per 1000. The death-rate amongst infants under the age of 1 year was 344 per 1000. This, though still very high, is the lowest for the past seven years, the decrease having been sustained since 1905. The reasons assigned for this high death-rate amongst infants are malaria, carelessness in the management of childbirth, insanitary surroundings, and ignorance as to feeding and clothing and cleanliness of children. Native children are not weaned until they are about 18 months old, but the natural food of the child is supplemented at an early age—a few months after birth in the case of the poorer natives—by a gruel made of maize. This is given to very young children, the mother "drenching" the child with it. In the meantime the high infant death-rate is a matter of great importance to the Sierra Leoneans, as, owing to the fact that the deaths are considerably in excess of the births, the race is gradually dying out. The natives all realise this, the more intelligent also realising that unscientific midwifery plays a prominent part in the matter. Some years ago the Government opened a special midwifery ward at the Colonial Hospital, and at first it was little used. Now, however, the natives of all classes, even the highest, make use of it, and it is hoped that its good effects will be as far-reaching as they are beneficial. The general health of the Europeans (who number about 620) was satisfactory, and the death- and sick-rates were below the average. There was no outbreak of small-pox, though a few cases were reported in the Protectorate. This disease, which was looked upon so recently as in 1907 as an "annually recurrent disease which usually makes its appearance in the dry season," appears to be gradually disappearing, a fact which can only be attributed to the action the Government has taken towards the prevention of the disease. Vaccine lymph is sent out fortnightly from the Liverpool Institute of Comparative Pathology. The total number of persons vaccinated in 1909 was 7443 as compared with 4317 in 1908. Of the former number 6491 were successful, 430 were unsuccessful, and 522 were not seen again. Lymph deteriorates very quickly in this climate, and the unsuccessful cases are attributed to the delay, owing to difficulties of transport, in despatching the supplies to their respective destinations. Great attention is being paid to sanitation generally and anti-malarial sanitation in particular. Hill Station, which is half-an-hour by rail from Freetown, undoubtedly justifies its existence, and is the finest and most successful anti-malarial measure carried out so far by any West African colony. There were 54 residents there during the year. The chief characteristics of Hill Station from a health point of view are—(1) its marked freedom from mosquitoes and most other winged insects, these being only very occasionally seen or heard; (2) its coolness and breeziness, especially at night; and (3) its restful quiet at night compared with residence in or near a native town, where the nights are made hideous by the barking of dogs, the beating of tom-toms (which, however, stops in Freetown at 9 P.M.), and the heat and stuffiness of the atmosphere. It is a great pity that it is not possible for all officials working at headquarters to reside at Hill Station, and if only it were possible for the public offices to be erected on the site the extension of the term of residential service could be considered. The native chiefs and their people in the Protectorate seem eager to carry out the suggestions made through the District Commissioners and medical officers for the improvement of their towns. Every year the Government awards prizes to the chiefs of the two towns in each district which have shown the greatest improvement in sanitation. These prizes, when won for the first time, take the form of very handsome swords with gilt hilts and scabbards, and the swords already awarded have stimulated other chiefs to improve their towns with a view also of obtaining swords themselves. When a prize is won a second or third time a parchment certificate is given to the winner of the prize. The chiefs are informed that if they allow the towns in respect of which prizes have been given to relapse into their original unsatisfactory condition the much-coveted swords will be taken away from them. Elementary hygiene continues to be taught regularly in all the secondary schools.

The climate of Sierra Leone is unhealthy and unsuitable for Europeans, but a more careful mode of living, and the adoption of precautions against the bites of mosquitoes, have done much to lessen the danger of the climate. The conditions of leave under which European officials serve—viz., four months' leave in England after a residence in Sierra Leone of 12 months—also materially affect the question of climate as far as these officials are concerned. There are only two seasons—the wet and dry—the former commencing in May and lasting until October. The lowest temperature last year was 67° on July 27th; the highest 99·4° on Feb. 12th. The total rainfall during the year was 139·97 inches.

The Colonial Hospital, Freetown, contains six wards with 62 beds. 1214 patients were admitted during the year. 217 surgical operations requiring the use of anæsthetics were performed during the year, this number being the highest on record. Only eight deaths took place in connexion with these operations. The number of out-patients treated at the Colonial Hospital during the year was 27,474. The records show a marked increase in the number of out-patients treated from year to year. Fifty cases were admitted during the year to the nursing home, a building in the town in the neighbourhood of the public offices. In the Male Incurable Hospital there were 78 patients at the beginning of the year, and 75 were admitted during the year. The deaths numbered 45, due chiefly to old age, syphilis, paralysis,

and exhaustion. There were six lepers in the hospital at the beginning of the year and two admissions in 1909, making a total of eight under treatment. There are hospitals and dispensaries at the headquarters of all the districts of the Protectorate. 428 cases were treated in these hospitals in 1909. The number of out-patients treated in the various dispensaries of the Colony and Protectorate (exclusive of the Colonial Hospital, Freetown) during the year amounted to 20,481.

Incidental allusion is made in the report to the extensive use by the natives in the Protectorate of kola nuts (much grown in the interior) as a tonic stimulant. "One nut well masticated and eaten will sustain a man for a whole day without food. The nut has no intoxicating or reactionary effect, though it has a very bitter and astringent taste."

TOOTHBRUSH DRILL.

To the Editor of THE LANCET.

SIR,—Will you kindly enlighten an interested reader with respect to the meaning of the term "hyd. perchlor." which appears at p. 76 of your issue of Saturday, July 2nd, 1910, in a communication entitled "Toothbrush Drill," signed Edward Carnall, M.R.C.S., D.P.H.?

If "hyd." is an abbreviation for hydrogen, I am not familiar with its perchlorid, which leads me to suspect that "perchlor." may be a misprint and that peroxid is what was intended. Or if hydrargyri perchloridi is what is intended, I would respectfully suggest that in view of the well-known poisonous qualities of corrosive sublimate, especially when used in oral work, it would be well to designate that compound with rather less ambiguity than your correspondent has done in order to avoid serious or even fatal results which might readily arise from this careless method of dealing with such a powerful poison.

And may I also add that practical experience has shown that a much more dilute solution of sublimate is amply sufficient to sterilise a toothbrush, even 1 in 10,000, if used long enough and in sufficient volume. And further, that a weak solution of formol, because of its non-toxic character, is a much more suitable toothbrush antiseptic in any event than is corrosive sublimate.

I am, Sir, yours faithfully,

Philadelphia, Sept. 20th, 1910. EDWARD C. KIRK.

*** Perchlor. was not a misprint, and the abbreviated term, rightly or wrongly, is in such daily use in this country that we cannot imagine the risk mentioned by Dr. Kirk to exist.—ED. L.

A DISTINGUISHED AGGREGATE.

Messrs. Burroughs, Wellcome and Co. have obtained what is believed to be a record number of distinctions in an exhibition of international character. The products of this firm have been awarded eight grand prizes, three diplomas of honour, and one gold medal at the Brussels International Exhibition.

STONE-BLIND.

To the Editor of THE LANCET.

SIR,—I have only to-day, on my return from holiday-making, seen my file of LANCETS published during my absence, and have read Dr. H. L. Gregory's ingenious suggestion with interest but without conviction. Of course, I had not forgotten Shakespeare's contribution to the subject, but confess had never thought of it but as a playful expansion of the idea such as might be expected from the character who, in the same sentence, speaks of his "true-begotten father." Apart from this I do not remember the expression "gravel-blind," and "sand" I took to be a popular mispronunciation of the A.-S. sam = half.

Dr. Gregory *may* be right (I am not an authority), but if he is right we should expect to find not only "stone-deaf" but "gravel-deaf" and "sand-deaf"—or with the analogous "deaf as a post," "deaf as shavings," "deaf as sawdust," and so on! But we don't.

I am, Sir, yours faithfully,

Cavendish-square, W., Sept. 27th, 1910. J. Y. W. MACALISTER.

FOURTH OF JULY CASUALTIES IN 1910.

THE *Journal of the American Medical Association* of Sept. 3rd contains a note on the number of deaths and injuries from the use of fireworks during the celebration of the Fourth of July. The casualties are decidedly less in number than heretofore. There were only 72 cases of lockjaw this year, where last year there were 150. This is the lowest number of tetanus cases reported since our contemporary began the compilation of these statistics in 1903. The *Journal of the American Medical Association* says: "There were 131 deaths this year as compared with 215 last year, and 2923 injuries this year as compared with 5307 last year. This remarkable decrease in deaths and injuries is undoubtedly due to the adoption by a number of cities, such as New York, Chicago, Boston, and Toledo, of restrictive measures, whereby the number of casualties was largely reduced, and also by the adoption of prohibitive measures by a number of cities, such as Baltimore, Washington, Cleveland, Trenton, and others, whereby deaths and injuries were entirely prevented or reduced to the minimum. A large number of cities also furnished special programmes in which music, the marching of soldiers, the flying of flags and banners, children's parades, historic floats, &c., were prominent features. This more sensible method of celebration of the Fourth of July is rapidly coming into vogue."

Antisweater has omitted to send his name and address. An answer will be sent him on receipt of the information.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Oct. 1st–5th (Paris).—Second International Conference for the Study of Cancer.
" 3rd–7th (London).—Sixth London Medical Exhibition.
" 3rd–7th (Berlin).—International Congress on the Care of the Insane.
" 4th–8th (Brussels).—Second International Congress of Alimentary Hygiene.
" 5th–8th (Brussels).—Ninth International Tuberculosis Conference.
" 10th–15th (London).—Town Planning Conference.
" 13th–15th (Paris).—Eleventh French Congress of Medicine.
" 16th–22nd (Barcelona).—First International Spanish Congress of Tuberculosis.
Nov. 7th–12th (Cape Town).—Twelfth South African Medical Congress (1910).

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Mr. W. Fox: Clinique (Skin). 5.15 P.M., Lecture:—Dr. R. Jones: The Teaching of Insanity in the British Isles.

TUESDAY.—4 P.M., Dr. H. Campbell: Clinique (Medical). 5.15 P.M., Lecture:—Dr. Scanes Spicer: The Causation and Care of Obstinate Nasal Discharges.

WEDNESDAY.—4 P.M, Mr. A. H. Tubby: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. R. Lake: Eustachian Obstruction.

THURSDAY.—4 P.M., Mr. E. L. Evans: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D. Grant: Some Practical Points in the Diagnosis and Treatment of Tuberculosis of the Larynx.

FRIDAY.—4 P.M., Mr. E. K. Campbell: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Dr. D. Grant: Methods of Examination.

FRIDAY.—3.45 P.M., Lecture:—Dr. D. Grant: Methods of Examination.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE CHEST, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Essentials in the Study of Dermatology.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (5th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (6th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (8th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. I. of 1910, which was completed with the issue of June 25th, were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1910 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The Huxley Lecture

ON

THE HEREDITARY ASPECTS OF NERVOUS AND MENTAL DISEASES.

Delivered at the Opening of the Winter Session at Charing Cross Hospital on Oct. 3rd, 1910,

BY F. W. MOTT, M.D. LOND., F.R.S., F.R.C.P. LOND.,

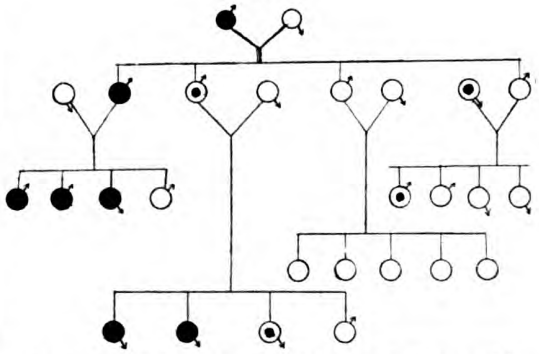
PHYSICIAN TO THE HOSPITAL; PATHOLOGIST TO THE LONDON COUNTY ASYLUMS; FULLERIAN PROFESSOR OF PHYSIOLOGY, ROYAL INSTITUTION.

MR. CHAIRMAN,—Permit me to thank you and my colleagues of Charing Cross Hospital Medical School most cordially for the great honour conferred upon me by the request to deliver the Huxley Lecture this year. When I look back on my distinguished predecessors I feel that, with this honour, there is a great responsibility, for it is not an easy task for me to deliver a lecture worthy of the occasion; and I felt, therefore, some difficulty in the selection of a subject. I was, however, guided in my selection of the hereditary aspect of nervous and mental diseases by the following facts. Heredity is a subject that the master mind of Huxley illuminated in several of his essays, and it is fundamental in the study of the Origin of Species and Natural Selection, which he did so much to forward. Next, recent developments in our knowledge of the subject of heredity owing to the labours of Galton, Pearson, and their followers in the study of biometrics, and Bateson and his followers in Mendelism, have aroused the keenest interest in the subject of human inheritance, not only in the medical profession, but in the thinking and intellectual portion of the nation. Another reason was that none of the illustrious lecturers in the past have dealt with the subject of heredity in relation to disease. Lastly, it is a subject to which I have recently devoted a large amount of attention in the study of the causation of nervous and mental diseases, and more especially the relation of heredity to various forms of insanity. The wealth of material in the London County Asylums has permitted a biometric investigation in a novel manner. The subject is one of national importance and interest, and it affects many social and legislative questions. The interest taken by the general public in the question of heredity is a sign of social progress. People are recognising the truth of Thomson's saying, "The present is the child of the past; our start in life is no haphazard affair, but is vigorously determined by our parentage and ancestry; all kinds of inborn characteristics may be transmitted from generation to generation."

DOCTRINES OF HEREDITY.

Fifty years have elapsed since Huxley wrote an essay on the Origin of Species in the *Westminster Review*, and the doctrine of Natural Selection which he upheld with such remarkable force remains unshaken and unshakable, but mutation or discontinuous variation has replaced in great measure the continuous accumulation of small differences to which Darwin attributed so much importance in evolution; and it is interesting to note that Huxley in this same essay said, "Mr. Darwin's position might, we think, have been even stronger than it is, if he had not embarrassed himself with the aphorism, *Natura non facit saltum*, which turns up so often in its pages. We believe that nature does make jumps now and then, and a recognition of the fact is of no small importance in disposing of many minor objections to the doctrine of transmission." Huxley cites the case of the Ancon sheep, also an interesting pedigree of polydactylism narrated by Réaumur. I will show a diagram (Fig. 1) illustrating this condition in three generations. Réaumur narrates this case only as far as the third generation, and Huxley remarks: "Certainly it would have been a curious thing if we could have traced this matter any further; had the cousins intermarried, a six-fingered variety of the human race might have been set up." In the light of the Mendelian law of gametic segregation even this would not be necessary, for a variation is "not swamped out." But sexual selection would tend against the perpetuation of this variation, which does not serve a useful purpose, nor is it an ornament. Huxley in another essay on Hereditary Transmission and Variation refers to the different product of crossing a stallion with a she ass, and a male donkey with a mare. "Here you see is a most curious thing; you take exactly the same elements, Ass and Horse, but you combine the sexes in a different manner and the result is modified accordingly. Here, then, is one and perhaps a necessary cause of variation." There is in these instances a prepotency of the male in certain physical characters; for on the one hand when the donkey is the sire a mule is produced with the head, ears, and voice resembling that

FIG. 1.



Polydactylism. The circles with black centre indicate partial polydactylism. The black circles are complete polydactylism. The chart is very suggestive of Mendelism.

animal, when on the other hand the horse is the sire a hinny is the product, with head, ears, legs, and voice like the horse.

Again quoting Huxley: "A certain amount of variation is the necessary result of sexual propagation itself; for inasmuch as the thing propagated proceeds from two organisms of different sexes and temperaments, and as the offspring has to be either of the one sex or the other, it is quite clear it cannot be a diagonal of the two or it would be no sex at all; it cannot be an exact intermediate form between that of each of its parents; it must deviate either to one side or the other. You will have noticed how very often it may happen that the son shall exhibit the maternal type of character, or the daughter possess the characteristics of the father's family."

The law of ancestral heredity of Galton supposes that every ancestor of a particular individual contributed its quota to the heritable qualities of the individual. The law also states that the average amount of resemblance between an individual and any particular ancestor is capable of definite numerical expression. Thus the mean amount of correlation between (1) the two parents and the offspring; (2) the four grandparents and that offspring; and (3) the great-grandparents and that offspring, and so on backwards in the ancestral lineage, is believed to diminish in a geometrical series one-half, one-quarter, one-eighth, which is the same for all organisms and their characters. Pearson represents a more rapidly diminishing series: (1) for the two parents, 0·6244; for the grandparents, 0·1988; for the great-grandparents, 0·0630, &c. We thus have a mosaic of ancestral characters.

It is quite possible that the above represents correctly the average total contributions of ancestors when applied to the race as a whole, but it cannot be universally applied to individuals, for, according to Mendel's theory of inheritance, certain ancestors may contribute nothing to the constitution of certain offspring in respect to certain characters. Moreover, as Maudsley truly says, it is a conclusion which, however true on the average of such simple characters as height, is manifestly not true of individual cases. Anyone selecting for observation different characters—e.g., noses or ears—can see plainly the nose may be like the father's or the mother's, or perhaps one of the grandparent's or further back. This fact was well known to the ancients, and, according to modern ideas of heredity, there is not much to be said against the teaching of Lucretius.

"Sometimes, too, the children may spring up like the grandfathers, and often resemble the forms of their grandfather's fathers, *because the parents often keep concealed in their bodies many first beginnings mixed in many ways, which first proceeding from the original stock*, one father hands down to the next father and then proceeding from these, Venus produces forms after a manifold chance and repeats not only the features but the voice and hair of forefathers, and the female sex equally springs from the father's seed and males go forth equally from the mother's body, since these distinctions no more proceed from the fixed seed of one or other parent than our face and bodies and limbs. Again, we perceive that the mind is begotten along with the body and grows up together with it, and grows old along with it." The individuality of every human being depends upon the mingled natures of two separate parents, and Goethe poetically refers to his own hereditary endowments in the following lines:—

"Vom Vater hab ich die Statur,
Des Lebens ernstes Führen,
Vom Mütterchen die Frohnatur
Und Lust zu fabulieren."

According to the Mendelian doctrine of dominant and recessive, the corresponding character of the second parent always exists in the offspring side by side with the character which finds expression, only the former, termed recessive, is obscured by the latter, the dominant. This is the explanation of a characteristic feature of a particular grandparent which was not visible in the parent reappearing in the child (*vide* Fig. 1). It also accounts for those heritable diseases and abnormalities which are transmitted by the females in ancestry and appear in the males—e.g., hæmophilia, Daltonism, pseudo-hypertrophic paralysis. As it passes from a father through a daughter to a grandson, and so on, it must be latent in the germ cells (concealed in the body) though for some obscure reason it has not found expression. In fact, non-expression of a disease does not necessarily imply non-inheritance of a disease, rather a predisposition to disease. It is well known that a hereditary tendency to nervous disease may have different expressions in successive generations—e.g., insanity and epilepsy; the hereditary transmission of nervous or mental disease is rather of the nature of a neuropathic tendency, the character of the disease being largely determined by the exciting cause. I have not time to discuss further the large question of Mendelism in relation to human inheritance, so far I have not met with any cases in entire support thereof, in the study of the hereditary aspect of nervous and mental disease, but, as pointed out by Professor Bateson, there are many reasons why it has not been found applicable. Of its enormous importance to biology and heredity there can be no question; even Professor Pearson, its most strenuous opponent, said, "The importance of Mendel's work and his followers lies in the observation of segregation"—this great fact holds whether Mendelism in its simple form remains or not.

THE RARER NERVOUS DISEASES AND HEREDITY.

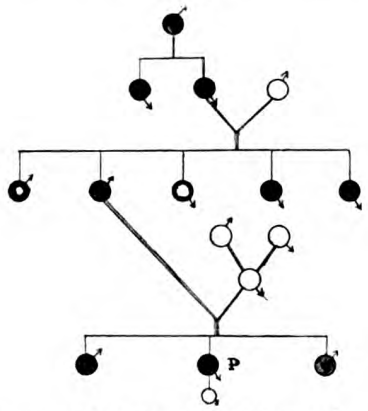
Among the rarer nervous diseases in which it is generally recognised that heredity plays an important part may be mentioned myotonia congenita, pseudo-hypertrophic paralysis, progressive muscular dystrophy (especially the Landouzy-Dejerine facio-scapular type), the neuritic type of progressive muscular atrophy, hereditary ataxia, Huntington's chorea, and family periodic paralysis. In nearly all the recorded cases of myotonia congenita (Thomsen's disease) the disorder has existed in several relatives of the patient, generally in one of the parents and in the patient's brothers, sisters, and children. More than 20 cases of the kind occurred in the family of Dr. Thomsen in four generations. It is to him that we owe the first accurate description. As in Huntington's chorea (a remarkable pedigree of which I shall show you), other neuroses frequently occur in the family tree. Many of Thomsen's relatives were affected mentally. Sir William Gowers in the recent discussion on heredity in relation to disease at the Royal Society of Medicine referred to the frequency with which pseudo-hypertrophic paralysis is hereditary; he likewise pointed out that the disease is characterised by sex limitation, and cited a very remarkable case, in which the disease, although not affecting the females, passed through to the males in several successive generations; there were two families and probably both originated in the same stock. Again, he referred to a remarkable case of facio-scapulo-humeral atrophy (Landouzy-Dejerine type) which could be traced for six generations.

Family periodic paralysis is a rare disease with a well-marked hereditary tendency. It is characterised by periodic attacks of more or less extensive flaccid motor paralysis with a loss of electrical excitability in the paralysed muscles and of the reflexes, but without sensory affection or disturbance of consciousness. Between the attacks the patient is well. In a family recorded by E. W. Taylor there were 11 cases in one generation; in the family of a patient of Goldflam there were 11 cases on the maternal side, and Holtzapple observed 17 cases in four generations. The disease may be transmitted indifferently through the father or the mother, although occasionally there has been limitation of transmission to the same sex. As in other diseases with a similar hereditary character, individual cases may occur in which there is no family history of the disease. A remarkable case of neuritic progressive muscular atrophy, showing that it might be of a hereditary character, was reported by Herringham; the disease was transmitted by females, but only males were affected. The disease, however, may be transmitted by both males and females, and both sexes are affected.

Friedreich's disease, although called hereditary ataxia, is seldom directly hereditary—it is a familial disease. Several families and several isolated cases have come under my observation, but in the isolated cases no family history of the disease in ascendants was found, nor was it in the two cases affecting a number of members of the family; in one of these there was a history of consanguinity, the parents of this family of hereditary ataxia cases being first cousins. A remarkable pedigree of hereditary ataxia worked out by Sanger Brown, however, shows the disease occurring in five generations of a family. Gordon Holmes states that Schoenborn found a family incidence in 114 of the 200 cases he analysed. Yet in a not inconsiderable number of recorded cases the same disease occurred in the ascendants or in the collateral lines. It may be transmitted through either males or females. Occasionally there is not direct heredity, but the disease occurs in families in which there seems to be a proclivity to spinal disease; for instance, a pedigree which I obtained at Darenth Asylum showed this relationship; moreover, occasionally, as this pedigree showed, it may be associated with idiocy. Nolan and Pritzsche have recorded cases associated with progressive idiocy.

I will now pass on to the consideration of a disease which I have met with occasionally in the asylums—viz., Huntington's chorea, in which a direct heredity has been found practically in all the cases studied. The accompanying pedigree (Fig. 2) is a striking one kindly furnished to

FIG. 2.



Paternal great-grandfather suffered with chorea—also paternal grand-mother and sister. Two paternal aunts and father suffered with chorea and died in asylums or infirmary—brother and sister physically unsound. P., the patient chorea and insane, one brother in asylum and one died. It will be observed that the maternal side is quite free from any taint.

me by Dr. C. H. Bond of Long Grove Asylum, under whose care is the patient of the fourth generation. Huntington, who first gave a complete picture of the disease, and after whom it was named Huntington's chorea, remarks:

"If one or both of the parents have shown manifestations of a serious nature, one or more of the offspring almost invariably suffer from the disease if they live to adult life, but if by any chance these children get through life without it, the thread is broken and the grandchildren or great grandchildren may rest assured that they are free from the disease. Unstable and whimsical as the disease may be in other respects, in this it is firm; it never skips a generation to manifest itself in another; as soon as it has yielded its claims it never regains them." Huntington also remarks upon the presence of the nervous temperament in all, or nearly all, of the families in which there is the taint of this disease, and says "that nervous excitement to a marked degree almost invariably attends upon every disease these persons may suffer from, although they may not in health be over nervous." Heilbronner states that there is a tendency in successive generations for the onset of the disease to be delayed, and Wollenberg has shown as this pedigree very clearly indicates, that choreic heredity in some cases may be transformed into other neuroses—i.e., epilepsy, imbecility, paranoia, grave hysteria, &c. Wollenberg has collected statistics of 128 cases in 22 families, of which 74 were in men and 54 in women, thus confirming Huntington's statement that it is more common in men than in women. Again, it was observed by Huntington that "the tendency to insanity, and sometimes that form of insanity which leads to suicide, is marked, and the mental condition usually terminated in dementia." In several cases a microscopic examination revealed a marked neuronic atrophy, with some neuroglia hyperplasia of both the frontal lobes, including also the central convolutions. Changes in the Betz cells have been described which might be correlated with the motor disorder manifested during life. I have observed changes of an abiotrophic character in the Betz cells in paramyoclonus multiplex affecting four members of a family; an uncle was an epileptic, but no other ancestral defect was discovered.

These forms of nervous disease are usually due to characteristic morphological defects, and for the most part are best explained by germinal defects in the specific vitality of groups of muscles or systems of neurons whereby they waste prematurely. Sir William Gowers has introduced the term of abiotrophy for this condition. From a practical point of view on account of their rarity abiotrophies are of little importance as compared with insanity and epilepsy, to which I shall now direct your attention.

EPILEPSY.

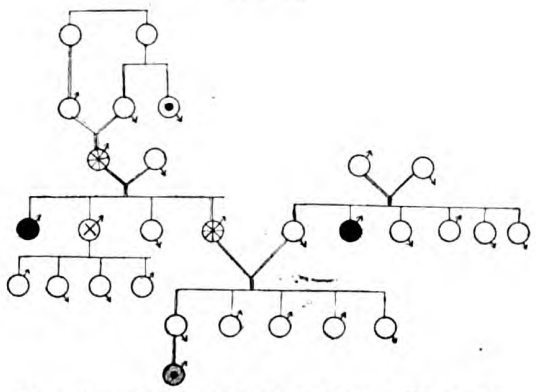
With regard to epilepsy I feel convinced from my own observations and experience that Sir William Gowers is correct when he asserts that there are few diseases in the production of which inheritance has a more marked influence and the traceable influence is always far less than that which exists. Voisin, Ferè, Nothnagel, Dana, Peterson, and Aldren Turner express similar opinions.

In the discussion of the subject of heredity and disease Sir William Gowers said: "In my own enquiries into the heredity of epilepsy I have limited myself to these two maladies, epilepsy and insanity. Heredity was ascertained in 39 per cent. of 1193 males and 43 per cent. of 1207 females. When epilepsy itself occurred in a parent it was the father who was epileptic in 49 per cent. and the mother in 51 per cent. The cases with insanity in a parent are only one-third the number compared with parental epilepsy. Of the cases with parental insanity the father was insane in 37 per cent. and the mother in 63 per cent. One effect of heredity is to increase the female cases. When it was absent the excess of males amounted to 4 per cent., but in cases of heredity the same excess was presented by females. This is partly due to the fact that inheritance is more frequently from the mother's side by 17 per cent., and that the females are in excess by 18 per cent." These facts (obtained by Sir William Gowers) are in many ways in striking conformity with the results obtained by my investigation of insane relatives in the London county asylums as regards certain types of insanity which I shall shortly relate. Moreover, I have observed that a similar heredity occurs in a considerable number of cases of insane epileptics, at least 20 per cent. Spratling from his large experience at Craig Colony gives 16 per cent. of similar heredity.

HEREDITARY CAUSATION OF INSANITY.

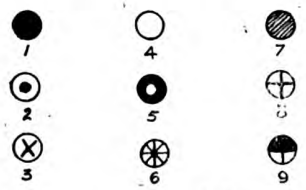
There are a few alienist physicians who do not have a strong belief in the hereditary causation of insanity, and my esteemed colleague, Dr. C. A. Mercier, at the discussion on heredity said: "When we are confronted with the percentage of persons among whose near relatives insanity is known to exist we cannot fail to be impressed with two remarkable facts, first how relatively small their percentage is, and second, that the statistics, even if taken at their face value, do not purport to be anything but an *enumeratio simplex* and cannot be made the basis of any valid conclusion until they are compared with similar statistics of the percentage of insane relatives among the sane." He also stated that the published statistics are of no value at all for any practical or scientific purpose. With this I would entirely agree, but in taking statistics among the sane population we should find that insanity and epilepsy would often occur in families where there are neuroses, eccentricity, and even genius, all of which were variations from the normal average of the species. I have endeavoured to ascertain what is the proportion of insane, feeble-minded, and epileptic members occurring in the pedigrees of my hospital patients; and I am greatly indebted to my house physician, Dr. W. R. Thomas, for the careful and painstaking way in which he has obtained information from the friends. In 32 pedigrees, which would include about 1000 living representative and 250 dead individuals, there were eight who had been in asylums and in eight others fits were chronicled. In no case was either parent of the patient insane or epileptic. Two of the pedigrees furnished most of the cases. (Fig. 6.) One was a patient suffering from neurasthenia in which there were, besides insanity and epilepsy, migraine, hysteria, deaf-mutism, and imbecility,

FIG. 3.



This pedigree shows a marriage of first cousins. The son possessed brilliant talents, likewise a grandson, but of two other grandsons, one was insane, another a suicide. The fourth generation are all sound.

The following is the key to this figure and all the remaining figures:—



1. Insane.
2. Physically unsound.
3. Suicidal.
4. Healthy.
5. Nervous disease.
6. Brilliant.
7. Died young.
8. Drunkard.
9. Drunkard and insane.

and the other a patient with exophthalmic goitre with several neuropathic members in the stock. I must confess that had I to prove my case by comparing the pedigrees thus obtained with some pedigrees obtained at the London County Asylums and Imbecile Asylum at Leavesden (20 non-selected pedigrees were kindly taken for me by Dr. F. A. Elkins and his medical officers), I should not have a very strong case, for in a very considerable proportion of the cases admitted to these asylums interrogation of the friends elicits no evidence of insanity on either side. Yet most alienist physicians would not agree with Dr. Mercier in casting doubt upon the importance of heredity in the production of insanity. I would rather say certain types of insanity. Many of the inmates of asylums

are suffering with congenital or post-natal organic brain disease; these conditions are certainly not due to inheritance. General paralysis of the insane, syphilitic brain disease, and softening from vascular disease are acquired conditions and should not be classed among the inherited insanities, nor should Korsakoff's psychosis and chronic alcoholism.

In all attempts, however, to ascertain what forms of insanity are especially due to inheritance there is always the difficulty of finding out by inquiry of the friends what was the nature of the insanity, not only because the friends do not know, but also because different opinions may be held by the medical men who have had charge of the cases, and different systems of classification and terminology have been used. Therefore, any statistical inquiry formed upon pedigrees the data of which are based *solely* upon information which has been obtained of friends of the patient may have several radical faults. The lack of statistical evidence of heredity in relation to feeble-mindedness was noticed by Sir Francis Galton in his comments upon the Report of the Commission on the Feeble-minded, and yet the opinion of experts was unanimous in favour of the importance of heredity as a causal factor.

Two years ago an experienced biometrician and scientist, Mr. Edgar Schuster, kindly undertook to coöperate with me in the study of the convolutional pattern of the brains of relatives dying in the asylums, with a view of seeing whether, just as there is a similarity of physiognomy in the members of the same family, there is also a similarity in the convolutionary pattern. An inquiry was initiated concerning relatives at the various asylums, and a request was made that brains of relatives should be kept for examination after the necropsies had been made. Isolated instances of two or more members of the same family were known to exist by me in the various asylums; but it soon became evident that a properly coördinated card system would reveal the fact that a *very large number* of parents and offspring and brothers and sisters, besides collateral relatives, were resident in the London County Asylums, or had been recently. In June the numbers had risen from a few hundred known instances to 1834 (763 males and 1071 females), and since then, owing to a newly opened asylum not having then furnished full reports, and owing to the fact that fresh cases are continually turning up at other asylums, the numbers have now reached 2000. These instances have been afforded by the records of patients under observation during the last two years, and include their relatives who have died in, or who have been discharged from, the London County Asylums previously. A large number of cases of recurrent insanity are included in these instances—e.g., one case has a record of 23 admissions—and during the time taken for the collection of the above cases several of them have been discharged and readmitted; but at the present time it is computed that over 60 per cent. of the relative cases are still resident in the London County Asylums. But this list does not include patients with relatives in the asylums of the Metropolitan Asylums Board, nor patients with relatives in other asylums in Great Britain and Ireland.

Before proceeding to give further details of the inquiry I wish to express my indebtedness to the clerk of the asylums and the superintendents and medical officers for the valuable assistance they have afforded me in obtaining information.

STATISTICAL DATA RELATING TO INHERITANCE OF INSANITY.

The 1834 cases are made up from 854 families as follows: 2 instances of 6 of a family, 3 instances of 5 of a family, 12 instances of 4 of a family, 85 instances of 3 of a family, and 752 instances of 2 of a family. Of the 752 instances of 2 of a family, making in all 1504 cases, it will be observed that the vast majority are directly, and not collaterally, related. Another fact stands out prominently in an analysis of the 752 instances of 2 of a family, and that is the much greater incidence of transmission from parents to offspring through the female side as the following figures show:—

Parental Heredity.

		Males.	Females.
Father and son	44 instances	88	—
Mother ,,	51 ,,	51	51
Father and daughter	58 ,,	58	58
Mother ,,	104 ,,	—	208
	297 ,,	197	317

It will be observed that the mother transmits to the offspring in the proportion of 60·7 per cent., the father 39·3 per cent. This is not accounted for wholly by the fact that there are more females in the asylums insane than males, for the ratio of females to males in the asylums is rather less than 11:8. Sir William Gowers in his statistics regarding insanity in the parents and epilepsy in the offspring observed that in cases with parental insanity the father was insane in 37 per cent. and the mother in 63 per cent. This, he says, is partly due to the fact that inheritance is more frequently from the mother's side by 17 per cent., and that the females are in excess by 18 per cent. It will be observed that these figures of mine closely correspond with his on the transmission of insanity from mother and father to offspring.

Cofraternal Heredity in Two of a Family.

		Males.	Females.
Two sisters	130 instances	—	260
Two brothers	87 ,,	174	—
Brother and sister	136 ,,	136	136
		310	396

The above table shows when pairs of offspring of the two sexes are affected the proportion of males to females is 43·9 per cent. to 56·1 per cent., a difference of 12·2 per cent. But the percentage in which the mother transmits insanity to the offspring as compared with the father is as 60·7 per cent. to 39·3 per cent., a difference of 26·4 per cent., and this increase of 14·2 per cent. is mainly due to the fact that she transmits to the daughter nearly twice as often as the father does. It may well be asked whether this may not partly be due to the fact that the daughter, at the time of life when insanity is manifested, is more at home than the son, and therefore has more to do with her insane mother.

Grandparents' Heredity.

Female with insane grandfather	1 instance.
Male ,, ,, ,,	1 ,,
Females with insane grandmother	6 instances.
Males ,, ,, ,,	5 ,,

This is undoubtedly very much below the proper ratio; it is due to the fact that there is far more difficulty of obtaining records. The hereditary transmission from females, however, markedly preponderates.

Collateral Insanity.

Female with uncle	12 instances	Male with uncle	11 instances
Female with aunt	33 ,,	Male with aunt	11 ,,
	45 ,,		22 ,,

There is here a more marked preponderance of females affected than males than in direct heredity, but the numbers are too few to draw any very decided conclusions, except the fact that the females with aunt affected are as numerous as all the rest combined.

The proportion of collateral relatives discovered in the London County Asylums is comparatively small for several reasons: the information is not so readily obtainable, and they are less likely to come into the same asylum, as their residence is not nearly so likely to be in the same district or county as that of parent and offspring.

I have analysed the above figures, only taking into account near blood relations (parents and offspring, brothers, sisters, or brothers and sisters) where two or more representatives of the family *are now* resident in the London County Asylums. The following figures show that of an average insame population of approximately 20,000, 717 cases are thus related, representing 342 families. We may ask the question, Should we find in 20,000 adults, living in the County of London, which some random non-inheritable cause had collected together, this proportion of direct relationship? I think not.

The figures, to my mind, in a broad way, are eloquent in favour of the importance of heredity as a cause of insanity, and the numbers being great, the data indisputable facts, independent of the personal equation of the inquirer, enable satisfactory statistics to be made and inferences to be drawn in regard to certain points relating to the hereditary aspect of mental disease.

Analysis of Instances where Two of a Family (near Blood Relations) are now Resident in the London County Asylums.

	Cases.		Cases.
Father and son	34	Two sisters	144
Father and daughter	58	Two brothers	80
Mother and son	44	Brother and sister	160
Mother and daughter	102		

making a total of 622 cases, representing 311 families. In addition to

the above there are 95 cases in which *three* (and in two instances four) members of the same family *are now* insane residents in the London County Asylums—31 families. Thus the grand total is 717 cases, representing 342 families.

TENDENCY TO INHERITANCE OF DIFFERENT TYPES OF INSANITY.

When taking part in the discussion at the Royal Society of Medicine on Heredity and Disease, I expressed the opinion that, without then being able to give any precise data, the investigation I was conducting had led me to conclude that we should find among these relatives in the asylums certain types of insanity exhibit a more marked tendency to inheritance than others, and I enumerated recurrent or manic-depressive insanity, delusional insanity and the insanity of adolescence (dementia præcox), and imbecility as having this tendency most marked. Moreover, I observed that cases of general paralysis were relatively few in number. In the light of modern views as regards the causation of general paralysis being due to syphilitic infection, I was not surprised to find my inference was correct. Again, in the evidence which I gave before the Royal Commission on the Feeble-minded I pointed out that during the eight years ending Dec. 31st, 1902, there were 8933 patients discharged from the London County Asylums as recovered; the percentage of readmissions was 25·59, and one-half of these cases were readmitted within 12 months of their discharge. The clinical records showed that a considerable number of these readmissions were cases of recurrent insanity termed "recurrent mania" and "recurrent melancholia"; the more modern term for this periodic insanity is manic-depressive insanity. But by whatever term it is called there is one feature—viz., periodicity. When I inquired into the family histories of these cases I found insanity in other members of the family in 55 per cent., even though I did not eliminate those cases which were not visited by friends, and there was no record regarding inheritance; moreover, I found particulars of many relatives of patients being in the asylum at the time or who had previously been in there or died there. These observations were made at Colney Hatch Asylum, where the superintendent, Dr. W. J. Seward, had for a long time been in the habit of taking the history himself from the friends who visited. I may add that this asylum has afforded valuable information in this research, partly because it is an old asylum with records often of three generations, and partly because, containing, as it does, all the Jews, one has the opportunity of comparing the incidence of inheritance of this race with the non-Jewish population. I am indebted to Dr. Seward for the following statistics relating to the percentage of relatives among the Jewish and non-Jewish population. The number of cards belonging to Jews is 80, the number belonging to non-Jewish inmates is 254. The total number of inmates is 2450, and of these 459 are Jews. So that rather less than one-fifth of the total population is Jewish. A little more than one-fourth of the relative cards belong to Jews, so that the incidence of ascertained relationship among the Jewish inmates is considerably more than among the non-Jewish. No doubt the temperament of the Jews renders them as a race more liable to the neuropathic tendency; but the greater incidence of ascertained relationship among the Jews is partly due to the following facts: They are more often visited by their friends. They have more pride of family, know more about their family, and, as a general rule, are more intelligent and anxious to afford information.

Statistics are often distrusted when an inquirer sets out to find something. I was therefore fortunate in having the coöperation of such an unbiassed statistician skilled in biometrics like Mr. Edgar Schuster. The cards were all sent to him for an independent and unbiassed investigation; his valuable report is published in the forthcoming annual report of the Asylums Committee, but I will summarise his results in great part in his own words.

There were 319 pairs of parents and children; of these the children in 69 cases suffered from periodic insanity. Of the 69 so afflicted 28, or 40·6 per cent., had parents similarly affected, while in 59·4 per cent. the nature of the parent's disease was different. Of the remaining 250 children only 41, or 16·4 per cent., had parents suffering from periodic insanity. Bratz working at Wuhlgarten Asylum, Berlin, on similar lines has obtained similar results, but as yet he has not published any statistics. He speaks of this similarity of insane inheritance as a Vererbungskreis.

There was even greater similarity of insane inheritance between brother and brother, between sister and sister, or between brother and sister, when suffering from this form of insanity, than between father and mother and son and daughter. Thus there were 200 pairs in which the first brother or sister was periodically insane, and in 92, or 46 per cent., of these pairs the second member also suffered with manic-depressive insanity, while in the remaining 108, or 54 per cent., the two members differed in the nature of their disease.

Where the first brother and sister suffered from some other form of insanity, in only 13·8 per cent., as compared with 46 per cent., was the other member afflicted with periodic insanity, while in 86·2 per cent. were other forms associated together. This indicates similar cofraternal inheritance more than three times as frequent in recurrent insanity as in other forms. Allowing that the term "recurrent" may have been used sometimes for a second attack of mania or melancholia which was not truly a manic-depressive insanity, still it would not account for this vast difference when dealing with such a number of cases.

Delusional insanity.—Although the numbers dealt with are many fewer, yet Dr. Schuster's statistics show that the tendency of this disease to run in families is more strongly marked than between parents and offspring. The tables he gives show that delusional insanity occurs with almost four times as great a frequency (33·3 per cent. instead of 9 per cent.) than among the insane parents of other insane people, while among the brothers and sisters the frequency is just six times as great (43·2 per cent. instead of 7·2 per cent.). There is a decided tendency for the brothers and sisters of imbeciles to be also imbecile.

In dementia præcox there is a strong correlation between members of the same cofraternity. Seeing, however, that quite 80 per cent. of the cases of this form of insanity occur before the age of 25, it is not surprising to find Schuster had no available material for statistics on parents and offspring. Perhaps the term "insanity of adolescence" is a better one than "dementia præcox." The report also shows a strong correlation between brothers and sisters when affected with chronic mania or melancholia, but the numbers are perhaps too small to draw any very definite conclusions.

With regard to general paralysis he found no indication of this disease running in families. The brothers and sisters of general paralytics seem no more likely than anybody else to be themselves general paralytics, and the same may be said about their children. Of the very few cases of juvenile general paralysis recorded, only one is the son of a general paralytic.

The second problem enunciated was, Is there any tendency for members of the same family (as in some hereditary nervous diseases) to become insane at similar periods of their lives? Seeing that adolescence is the period in which stress is likely to affect the individual with an insane inheritance, it is not surprising that Schuster in his report states that "a strong tendency exists for brothers and sisters of the same family to become insane at similar periods in their lives, and only a slight one between parents and children."

APPEARANCE OF THE BRAIN.

Since certain forms of insanity exhibit so much greater tendency to similarity of type in parents and offspring and brothers and sisters, it may be concluded that *these are the types* in which an inheritance of a tendency to insanity is three or four times as great as in other forms. Now we may ask ourselves the question, Is there any correlation between the macroscopic and microscopic appearances of brains of persons suffering from manic-depressive insanity, delusional insanity, epilepsy, and insanity of adolescence where there is no terminal dementia? It would be difficult in the vast majority of cases to discover any abnormal morphological change, nor would microscopic investigation afford much (if any) help in the elucidation of these psychoses. Indeed, I know of only one form of insanity that is really (as I have already said) an acquired organic disease—namely, general paralysis—which on macroscopic and microscopic investigation of the brain post mortem shows such change in the organ of mind as to justify a diagnosis of the form of

insanity which had affected the individual during life. I do not mean to say that these psychoses may not eventuate in a dementia, and then changes may be found in the brain.

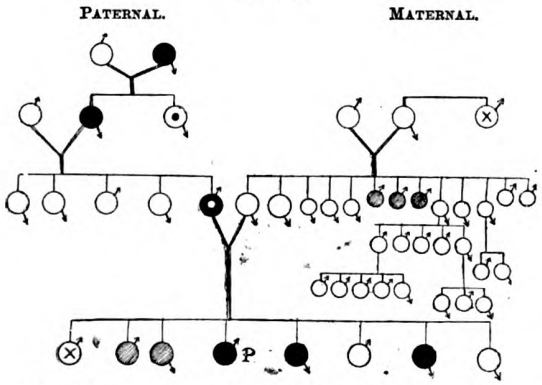
There is a disease affecting Jewish children which is quite specific in the changes observed in the brain and nervous system: I refer to so-called "amaurotic idiocy." Why it should affect only Jewish children and occasionally occur in several members of the same family is not known; nor is it explicable unless it be by an abiotrophy due to some racial hereditary condition. This disease shows a pathological change quite unlike any other disease of the nervous system that I have seen; the Nissl substance disappears from without inwards towards the nucleus, and eventually the nucleus itself dies and the whole cell undergoes a true fatty degeneration; the neurons which were the last developed are the first to go—thus the pyramidal layer of the cerebral cortex shows this fatty degeneration much more markedly than the subcortical neurons.

SOME PEDIGREES ILLUSTRATING INHERITANCE.

Every insane patient should be considered as a biological study. To say, merely, that one of his ancestors was insane and therefore he has a bad heredity, and to label him thus, as is the common custom, is absurd. What we wish to know is what he was born with and what has happened to him since birth. I have found that a conversation with the mother will very much help in understanding the causes which have led up to the mental breakdown, and she is often able and generally very willing to tell all she knows about the family. I am speaking only of the poorer classes.

The causes of insanity are seldom simple; they are in varied degrees inborn tendencies combined with some form of mental or bodily stress. I use the word "stress" in its widest sense as implying a strain on the important organs and functions of the body. But it is not within the province of this lecture to deal with these causes of insanity, for my object is to dwell upon the elucidation of what were probably the inborn tendencies. The construction of a pedigree will often answer the question, Did the patient come from a good stock on both sides, or was there physical or mental defect or both on maternal or paternal or on both sides? The fact that a cousin was insane, or even several members of a large stock, does not show a bad heredity; often, indeed, with several insane members there will be found men of genius and men and women of great civic worth (*vide* Fig. 3). A bad stock is where we find degeneracy, insanity, drunkenness, and criminality in the pedigree (Fig. 4), or a general low standard, mental and physical, in both stem and branches of the family tree. The general tendency is for insanity not to proceed beyond three generations, and I have only three such records. As a rule, there is either a regression to the normal or the stock dies out. Not infrequently the stock

FIG. 4.



The patient, P, was a murderer, a brother committed suicide, and two sisters were insane; although there was a suicide on the maternal side the insane tendency came mainly from the father's stock.

dies out by the inborn tendency to insanity manifesting itself in the form of congenital imbecility or insanity of adolescence —dementia præcox. (Fig. 5.) Such patients are especially prone to die from tuberculosis; thus "rotten twigs are continually breaking off the tree of life." (Figs. 8 and 10.) I will illustrate these facts by some examples of pedigrees.

Consanguinity does not appear to produce insanity or nervous disease provided both stocks are free from taint, but if there is insanity or epilepsy, not necessarily in the first ascendants, but even in the collaterals, then intermarriage of first cousins from these two stocks with collateral insanity will tend to insanity, in some cases very marked, in the offspring of the two sane related parents.

FIG. 5.

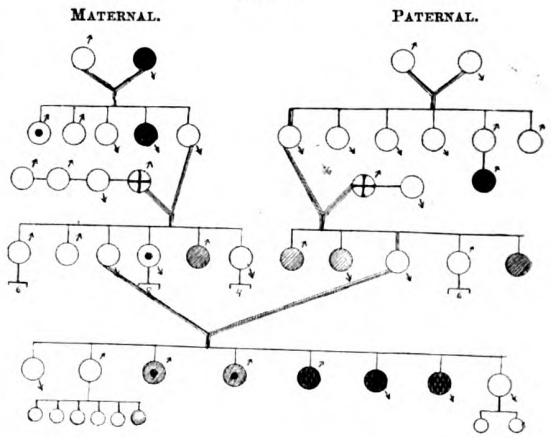


FIG. 6.

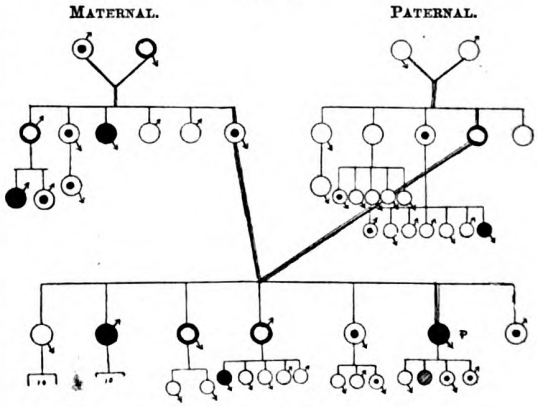
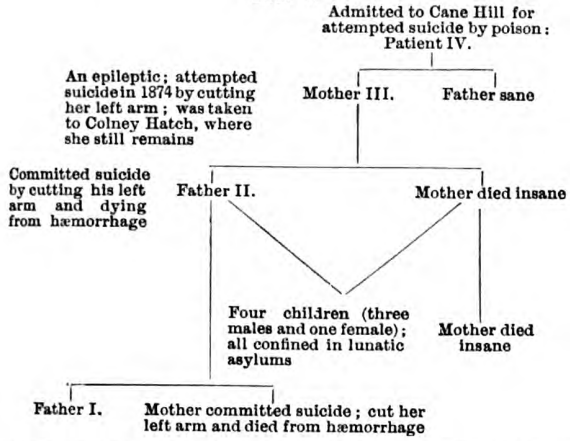


This pedigree is of a hospital patient P. suffering with neurasthenia and mental symptoms. It will be observed that nervous disease and insanity affect a number of members, especially on the maternal side.

I have observed in many of these pedigrees, but have not as yet compiled precise data, that manic-depressive insanity in a stock is frequently associated with suicide in the members so affected, and even in others not affected. The tendency to suicide often runs in families, and some remarkable pedigrees have been published in which members of families in successive generations have taken their lives in a particular way, and sometimes even at a particular age; there is a suicidal obsession. Morel mentions an instance where seven brothers destroyed themselves though in good position and suffering no misfortune. Mudge in the first number of the *Mendel Journal* has published a remarkable pedigree of two families that were united by marriage. In one the members committed suicide by drowning, the other by shooting. I would explain this by imitative suggestion acting on a neuropathic stock. A member of a family of four generations of suicides, of which two were inmates of the London County Asylums—namely, Colney Hatch and Cane Hill—and the pedigree of which I will now show you,

affords a striking example of suicide and insanity in successive generations:—

FIG. 7.



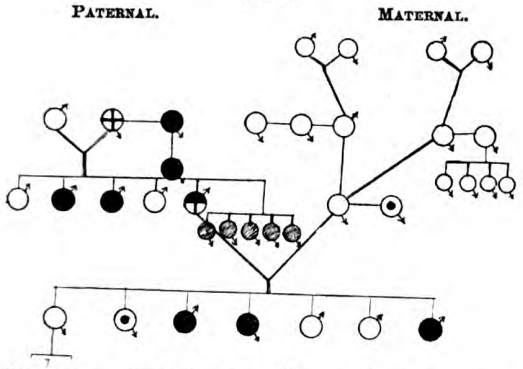
It will be observed that in three successive generations suicide was attempted or committed by cutting the left arm.

Another interesting case of a suicidal family in which a member developed impulsive obsessions of suicide and automutilation occurred at Cane Hill Asylum and was published by Dr. H. Devine, accompanied by interesting observations on the subject. The development of the obsessions in the patient dated from the aunt's suicide, which is a proof that suggestion was the cause, acting in conjunction with insane inheritance.

ALCOHOLISM.

The vexed question of transmission of acquired characters, specially in relation to alcoholism, is one of great importance and interest. That the germ cells are sequestered—"in the body and not of the body," therefore not participating in the biochemical changes which occur therein—and that in prolonged toxic conditions are uninfluenced in their nutrition and their specific vital energy, is contrary to reason. It may therefore be asked how it is, as so often happens, a chronic alcoholic may have offspring mentally and physically sound? The question is wrapped up in the causes which lead a man to drink, and my observations seem to show that a man who can drink continually for numbers of years and keep out of a lunatic

FIG. 8.

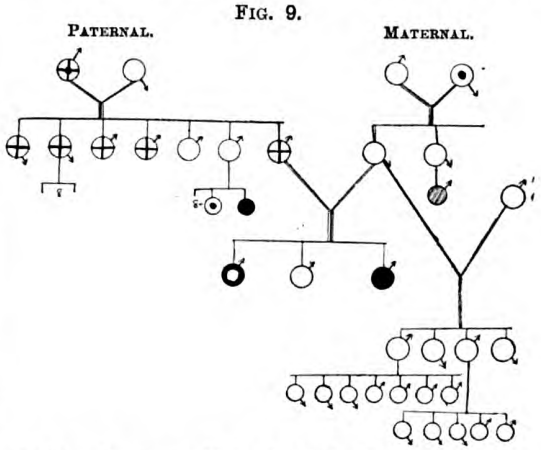


Drink and insanity in three generations; for description see text.

asylum, a prison, or a hospital, must have possessed an inherent stable physical and mental organisation, and he in a measure transmits this, the virility of the stock remaining potent in spite of the vicious habit, although it is undeniable that his offspring in all probability would have been stronger and better had he been a temperate man. Drunkenness in successive generations would undoubtedly lower the virility, and mental and physical degeneracy would result. Dr. Archdall Reid has expounded the tendency of the uncontrolled alcoholic type to work itself out and the same is true of other types.

I have often noticed that the children of chronic drunkards, especially when the father drank and the mother was temperate, are total abstainers. There can be no question that chronic alcoholism does figure largely in the pedigrees of patients admitted to asylums; but the same occurs—though I think not with such frequency—in the pedigrees of hospital patients. The accompanying pedigree (Fig. 8) was always regarded as a proof that alcoholism may be productive of insanity in several members of a family. The institution of the card system revealed the fact that there was collateral insanity (Fig. 8). I discovered that the sister of the drunken paternal grandmother died in Colney Hatch Asylum, where she was resident for 20 years, and her daughter, an imbecile, was at Leavesden. Further unbiased inquiries on these lines are very necessary. Occasionally I have met with a pedigree (Fig. 9), such as the one I show you, in

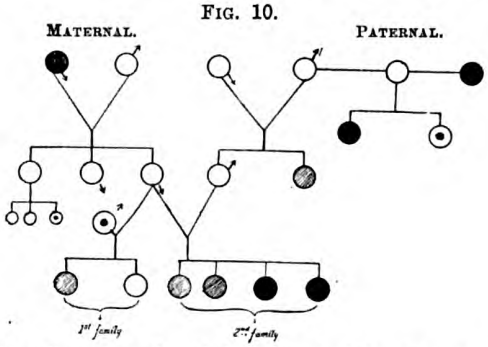
FIG. 9.



Pedigree of a woman with two husbands. By her temperate first husband a healthy stock; by her second drunken husband only one of them sound.

which a woman has had two husbands; by her first husband (a temperate man) she had a family of healthy children and numerous grandchildren; by her second husband (a chronic drunkard and one of a family of drunkards of several generations) she had three children, one with a muscular dystrophy, another an epileptic imbecile, and another apparently healthy. A few cases such as this may be a mere coincidence, but multiplied, seeing that they are almost of the nature of an experiment, would form a convincing argument in support of the injurious effects of alcohol on the germ cells. It has long been the opinion that chronic drunkenness of the parents leads to mental degeneracy in the offspring in the form of feeble-mindedness and epilepsy. With this I should

FIG. 10.



This pedigree shows the end of a degenerate stock. A woman of an insane stock marries twice; by her first husband there is one child living; by her second husband, presumably syphilitic, there are two born dead and two others in the asylum, one being a juvenile paralytic.

agree, but that the desire for alcohol is transmitted from parent to offspring, in the form of like begetting like instead of like begetting *a tendency* to like, is without foundation. What may be transmitted is the temperament

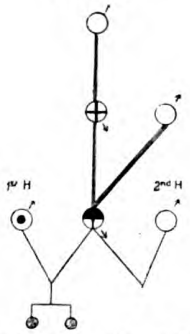
that induces alcoholism, a lack of will-power and moral sense. The transmission of an acquired character, such as the desire for alcohol, is contrary to the doctrine of heredity.

PEDIGREES OF IMBECILES, ETC.

In a number of pedigrees obtained from an imbecile asylum (Leavesden), for which I am indebted to Dr. Elkins, the superintendent, I observe (though the numbers are not sufficient yet to give any precise data) that the families are prolific, quite as prolific as those of the pedigrees of hospital cases, but there is relatively a larger number of deaths from various diseases, especially tuberculosis. Some family pedigrees show a large number of miscarriages and still-births associated with imbecility and epilepsy and occasionally juvenile general paralysis. The cause of this is syphilis. (Fig. 10.) The mental defect in a large number of these cases in imbecile asylums is undoubtedly due to organic brain disease and injuries at birth and after.

I have still another pedigree to show; it illustrates the transmission of a similar character and life in two generations and possibly three. (Fig. 11.) The grandfather was a

FIG. 11.



Two generations of drunken mothers and the stock of a great man is ended.

most distinguished man who lived to a great age, much respected. He had a daughter concerning whose mother no particulars were obtained. This daughter was a drunkard and of a defective moral character. She had a daughter who behaved in a somewhat similar manner, and is at present in an asylum; she has married twice. By her first husband she had two still-born children; by her second husband no children; fortunately this stock has died out.

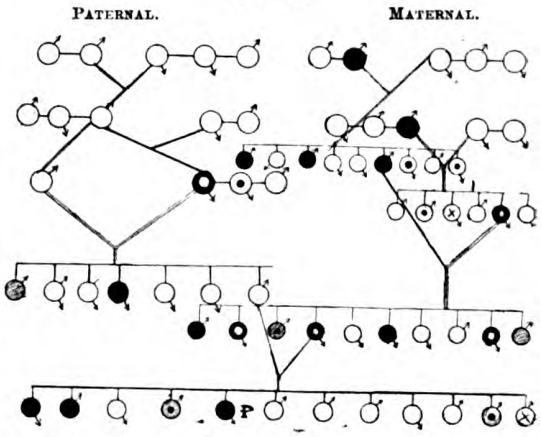
A study of pedigrees teaches us the truth of the conclusion which Maudsley emphasises in "Pathology of Mind": "First, that a person does not inherit insanity, but a tendency or predisposition; and, secondly, that the tendency is inherited from the stock." ..... "Nor need the unsound strain in the stock show itself in any form of actual insanity; it may appear in some allied nervous disorder, in hypochondriasis, in suicide, in epilepsy, in dipsomania, in weakness of mind, in neuralgias, in chorea, in stammering, in spasmodic asthma, in some periodical nerve storm of abnormal character; and conversely these disorders of one generation may in their turn forebode some form of insanity in the next generation." (Fig. 12.)

EUGENICS AND NATIONAL DEGENERACY.

With the spread of the knowledge of heredity and the interest shown among the intellectual and thinking classes by the study of such works as Whetham's "The Family and the Nation," more care will doubtless be taken in marriage selection; moreover, the cult of eugenics—literally good breeding—a term employed by Sir Francis Galton to denote the science and art of the improvement of the human race by the double process of multiplying the fit and eliminating the unfit—is daily gaining ground. Again, the study of heredity teaches that the measure of the physical, mental, and moral capacity of the individual for civic worth and usefulness depends largely upon inborn characters; you do not gather grapes of thorns or figs of thistles. Bateson has truly said, education, sanitation, and the rest are but the giving or withholding of opportunity. The diminishing birth-rate of the professional and middle classes with the high birth-rate and diminished infant mortality of the lower classes is now agitating the minds of many, but the fact nevertheless remains that Nature cares little about individuals or societies; it is mindful only of the species, and the instinct to propagate is so rooted in our animal natures that in the process of the mental evolution of man it has become the root and stem of the tree of life upon which have been grafted the moral virtues and altruistic sentiments which are most nobly personified in maternity. We can therefore understand how the Madonna and Child has appealed symbolically to the simple faith and devotion of countless millions.

An intellectual development, whether of the individual, or community, or race, that starves the natural instincts of love, marriage, parentage, and pride of family,—these, the noblest of all human aspirations, will pay the penalty, and

FIG. 12.



This pedigree of four generations is interesting on account of its completeness and by the large number of members of the stock on the maternal side which are affected with insanity, nervous diseases, and suicide; but there is not a single alcoholic on either the paternal or maternal side. The paternal stock is not free from taint, but the three cases of insanity and the suicide of the fourth generation, making up nearly half the living members, have for their parents a healthy father and a mother with nervous disease. It shows how necessary it is to study the maternal and paternal pedigrees in coming to any just conclusion about hereditary transmission.

one way in which the penalty for the starvation of this instinct will be paid for by advanced civilisation is the increase of the neurotic, self-regarding type of temperament, the forerunner frequently of neuroses and insanity.

We are constantly reminded of the fact that insanity is on the increase; in the last 15 years the London County Council has opened four new asylums and an epileptic colony, and is now building another huge asylum; loud is the cry of national degeneracy, but when people are feeling most pessimistic about a *natural* decay of the race it would be well, if they would remember this passage from a lecture by Huxley on "Harvey and the Discovery of the Circulation of the Blood": "I myself am of opinion that the memory of the great men of a nation is one of its most precious possessions—not because we have any right to plume ourselves upon their having existed, as a matter of national vanity, but because we have a just and rational ground of expectations that the race which has brought forth such products as these may, and in good time, under fortunate circumstances, produce the like again. I am one of those people who do not believe in the *natural* decay of nations, I believe, to speak frankly, that the whole theory is a speculation invented by cowards to excuse knaves. My belief is that so far as this old English stock is concerned, it has as much sap and vitality and power as it had two centuries ago, and that with due pruning of rotten branches and due hoeing up of weeds which will grow about the roots the like products will be yielded again. The weeds to which I refer are mainly three: the first of them is dishonesty, the second is sentimentality, and the third is luxury."

Abstracts
OF
INTRODUCTORY ADDRESSES, ETC.,
DELIVERED AT THE
MEDICAL SCHOOLS
AT THE
Opening of the Session 1910-11.

UNIVERSITY COLLEGE, LONDON.

INTRODUCTORY ADDRESS BY THE DEAN OF SALISBURY.

AT the opening of the Winter Session the chair was taken by Sir THOMAS BARLOW, President of the Royal College of Physicians of London, whose retirement from the active staff of University College Hospital has just been announced.

The DEAN OF SALISBURY said it was the admiration and affection with which he regarded medical men which compelled him to consent to undertake the responsibility and gave him his qualification in coping with the difficulty of addressing the students, teachers, and authorities of University College Hospital. He felt justified in saying that there never had been a clergyman who, during his tenure of a metropolitan living, had gathered around him in one church for nearly 30 years so large a number of men eminent in the medical profession as he had, and that fact was the pride of his life. It was the practice of his calling to take a text, as it was that of theirs to write a prescription. He would take as his text a section from the "Pensées" of Pascal, mathematician, physicist, philosopher, and man of science and ascetic piety: "Man is evidently made for thinking. This is his whole dignity and the whole of his merit. To think as he ought is the whole of his duty, and the true order of thinking is to begin with himself, his Author, and his end. And yet what is it that is thought in the world? Not one of these objects, but how to take pleasures, how to make ourselves kings, without ever reflecting what it is to be a king or even to be a man."

He impressed the necessity for realising the powers, potentialities, and special appetences with which man is endowed, but recognised that in this life time is wanting for a complete self-culture and development; and, moreover, the special subjects on which medical men must occupy the main power of their minds were impediments in the way of complete self-development, but concentration of all the mental energies in one direction must leave the other powers and capabilities of the mind unused and cause them to dwindle and die. Lord Morley had said: "One of the most narrow and what will eventually be one of the most impoverishing characteristics of our day is the excessive claims for physical science," from which other manifestations of intellectual activity need protection.

For artists, poets, and for many women such subjects as psychology, mathematics, and the exact sciences would tend to balance the mind and strengthen the judgment and make imagination the charm and not the master of life, but for them the realm of the fine arts was that into which they should make excursions for the refreshment and enlargement of their mental life. Some attention to architecture, painting, sculpture, music, and poetry should by a solemn determination always engage some of their energy. It might be said that such a discipline would only produce diletantism with variety for its inseparable accident; but was a little knowledge less desirable than complete ignorance or a dunce more admirable than a dilettante? Most of all he urged the claims of poetry and continued:—

Not so long ago one of the most learned scholars in Europe said to me, "Last time we met you did me a great service; you told me to read a little poetry every day, and I have done it ever since." If I could induce all you I have the privilege of addressing to go and do likewise you would think of me with gratitude when I am no more. For poetry is the queen of the arts. It is the thought, the vision, the emotion, of some powerful mind vitalised by imagination and expressed in that mode of music we call rhyme or rhythm. People who say that the subjects of poetry can be more effectively told in prose do not know what they are talking about. They are as wise as a blind man who denied the charm of colour or one incapable of perceiving odour the sweetness of the violet and the rose. It was a doctor of medicine who wrote the play called *The Good-natured Man*. It was Oliver Goldsmith. Jack Lofty, on hearing the name of the poet Waller exclaimed: "Is he of the house?" Mrs. Croaker replied: "The modern poet of that name, sir." Jack: "Oh, a modern! We men of business despise the moderns; and as for the ancients, we have no time to read them. Poetry is a pretty thing enough for our wives and daughters; but not for us. Why now, here I stand that know nothing of books—I say, madam, I know nothing of books; and yet I believe I can talk my two hours without feeling the want of them." I suppose there may be found to-day people equally vain of their imbecility. What are some of the greatest names in history but the names of poets? In telling such names over who could leave out Homer, and Virgil, and Dante, and Shakespeare, and Milton, and Goethe? I have no patience with people who without shame say they do not care for poetry, for they say they do not care for some of the loftiest products of the human mind. If you have not at present a liking for poetry then make one. How can it be done, and so done as not to withdraw too much energy from your professional work? I should say choose a poet who is acknowledged by the weightiest authorities to be a true and great poet. Do not waste time on what are called the minor poets. Some of them in time may be placed among the major poets. But if you can have but little it is all-important you should have the best. Having chosen your great poet, and one not of your own generation, who can only idealise the age of which you are a part and represent yourself, then every day, even if it be but for five minutes, read a page. Read it carefully, noting every suggestive word and visualising every scene. When something pre-eminently expressive or melodious strikes you mark it with a pencil. Each day peruse your page, looking back on previous ones to re-impress what you have already noted. Do this; and not a year will have gone by without your growing keener to perceive beauty and more sensitive to the impact of its charm. A short time ago I was told that Wordsworth was little read by Oxford men. Well, there are men and men as well as ninth parts of men. I can scarcely believe that those university men who are destined to make a mark in the world, men of sound and wide attainments, can be indifferent to, or unacquainted with, this great poet—who, alas, was often a great proser. Too much metrical prose is to be found in his longer poems; but they have in them bursts of inspiration radiant as the sunshine gilding the lake he loved. Mr. Bradley, who was professor of poetry at Oxford, said of Wordsworth, "Indisputably the most sublime of our poets since Milton." John Stuart Mill, a man whose young life no sunshine of poetry brightened its dreary laborious days, speaks of Wordsworth's poems as "a medicine for his state of mind." He said "compared with the greatest poets he may be said to be the poet of unpoetical natures possessed of quiet and contemplative tastes. But unpoetical natures are precisely those who require poetical cultivation. This cultivation Wordsworth is more fitted to give than poets who are intrinsically far more poets than he." Try, I would say to those who at present are not students, still less lovers, of poetry, try Wordsworth's "Prelude" and "Excursion." One page a day, five minutes' meditation, proof by experiment; and I am sure that all except the organically and incurably dull, who are as incapable of poetic sensibility as a piece of putty for emitting music, in a single year will, without interfering with professional work, have evoked from hidden, unperceived, subliminal depths a poetic sensibility which will be an organ of ever-increasing delight. I am not suggesting that you should all attempt to become poets. I daresay many of you have written verses, and some fair being has placed them in her bosom and thought them beautiful. Well, what can be happier than to be in love! Imagination and emotional sensibility which belong to youth and ripening manhood are especially quickened by the ardours of love. They give glow and expression and poetic sensitiveness in the days when the heart is more than a muscle, and the eyes of a girl more than a study in optics. May you have no *cardiac* failure in this respect, and may your love and its gladness live longer than your verses. There have been members of your profession to whom has been accorded the name of Poet. But I have a suspicion that their eminence as poets

was inversely as their success in practice. Oliver Goldsmith was perhaps one of the best representatives of poetic accomplishment in the medical profession. It is uncertain where and how he obtained his medical degree, but it is scarcely possible to doubt that he did, in his foreign wanderings, receive a nominal qualification for practice. This must have been small and brief. It is said that he drew out a prescription for a certain Mrs. Sidebotham which so appalled the apothecary that he refused to make it up, and that as the lady sided with the apothecary he threw up the case and his profession at the same time. But what a delightful, fascinating writer Goldsmith is! All who have any poetic taste are charmed by the tenderness and simple yet perfect grace and music of the "Deserted Village." All who care for genial humour mingled with the restraining pensiveness of one who knows the sorrows of life as well as the eccentricities which provoke a smile are in love with the "Vicar of Wakefield." All who care for English comedy without vulgarity and without pruriency welcome the revival on the stage of *She Stoops to Conquer*. A story is told of Goldsmith that after visiting a very poor patient he gave him a very large pill-box, in which he had placed such money as he had, and on it the words "To be taken as occasion requires." Ah! I have forgotten a greater poet still—first almost in my opinion of the brilliant stars which shine in the firmament of the nineteenth century—I mean Keats. He studied medicine at St. Thomas's Hospital, and when his poems appeared vulgar reviewers tried to extinguish them by sneering at the author's medical training. "Go back to the shop, Mr. John; stick to plasters and pills and ointment boxes." ..... The poems live and the reviewer is everlastingly damned. I do not call upon you to devote yourselves to the production of poetry; suffice it to say that your minds should become, as it were, cabinets of beautiful things. Even if you had to limit your pecuniary gains for the sake of a complete development, would it be a serious loss? It was asked by one, who must be venerated by all, as He is worshipped by millions, "What is a man advantaged if he should gain the whole world and lose his own soul?" By losing the soul I mean losing the finer capabilities and potentialities of the thinking being, with all the gracious satisfactions which they produce, and by so much becoming less than man. There are thousands of things which are not necessary for happiness. A simple home where love and refined taste and mental accomplishments and social graciousness are established may be had on a comparatively small income. In many a humble clerical home, British and German, there is refinement of manners and intellectual accomplishment; there are sons and daughters in whom virtue, brains, and religion are worthily combined, who become strength and fibre in their native land. What more is necessary? That they should start life with a fortune? Better that they should make one. At any rate it is more to be a man than to be a money-bag. Those who think otherwise must be left to amass the most they can and then descend to a grave where gains of coins can never enter. What if there is afterwards a long life even for ever and ever! What to enter a spirit world with a pauper mind! I am not certain but an eight hours Bill enforced upon successful members of the learned professions might not be good for them, and certainly an advantage to those who have to wait until middle life before a real start in successful practice can be made. Perhaps there should also be fixed a time for retirement, as in the army and navy, in order to make way for younger practitioners, and afford opportunity to complete the neglected development of the elder. In a very interesting study of social conditions called the "Camel and the Needle's Eye" Mr. Ponsonby observes that "in all professions, arts, trades, and crafts, the fixing of a limit within which to operate, is the secret of the attainment of a high quality of work, because it is the recognition of human limitations." But dwelling upon a wider culture than that which may be had from professionalism, the culture which aims at the realisation of ideal manhood, I have had the privilege of recommending to you, I know you will pardon me if, as I conclude, I remind you that the æsthetic powers are allied to that highest and most complete mode of embodying all that is beautiful, all that is true, and all that is good, we call God. To combine these three ideals, the ideals of science, art, and ethics in one supreme unity is to set before ourselves an object to which the homage, the worship of our whole composite nature can wisely be rendered. No humiliating sense of littleness nor of puerility, nor of irrationality can shame the artist aiming at perfect beauty, the scientist and the philosopher at absolute truth, and the moralist at a supreme good, who offers up his worship; and worship, as Browning tells us, is "Loved and praised at height."

ST. MARY'S HOSPITAL.

INTRODUCTORY ADDRESS ON "THE ROMANCE OF MEDICINE," BY SIR ARTHUR CONAN DOYLE.

AFTER a few introductory words, in which he referred to his experiences as a medical man in a rural village, in the slums of great cities, in an Arctic whaler, in the neighbourhood of Cavendish-square, Sir ARTHUR CONAN DOYLE went on to say that a medical training was a most valuable possession for a man, even if he did not afterwards engage in practice. After a medical education all work in life, if done in the right spirit, became far more easy. He then referred to the undue materialism of the period when he received his education—a materialism which he thought was due to a reaction against transcendental dogmas. Mellow experience and riper thought, however, made a man realise that materialism did not explain everything, and he continued:—

"I would ask you then, gentlemen, in your studies of matter, not to be precipitate in your conclusions as to spirit. Keep your minds open on the subject. And besides an undue materialism, there is another danger upon which I would warn you. It is intellectual priggishness. There is a type of young medical man who has all his diseases nicely tabulated, and all his remedies nicely tabulated, the one exactly fitting the other—you produce the symptom, and he will produce the tabloid—who really is a very raw product. Life may turn him into a more finished article. Each generation has thought it knew all about it, each generation has in turn discovered its limitations, and yet with invincible optimism each fresh lot still thinks that they really *have* got to the bottom of the matter. Not only have we never got to the end of any medical matter, but it is only the truth that we have never got to the beginning of it. What we have done is to come in in the middle of it, with more or less accurate empirical knowledge. It will help to keep you humble if you remember how largely the very words we use, Life, Matter, Spirit, and so on, are mere symbols of the real meaning of which we know little.

There is another fact which life will teach—the value of kindliness and humanity as well as of knowledge. That is exactly the point which the intellectual prig has missed. A strong and kindly personality is as valuable an asset as actual learning in a medical man. I do not mean that trained urbanity which has been called 'the bedside manner,' but the real natural benevolence which may be slowly cultivated in the character, but cannot be simulated by any forced geniality. I have known men in the profession who were stuffed with accurate knowledge, and yet were so cold in their bearing, and so unsympathetic in their attitude, assuming the rôle rather of a judge than a friend, that they left their half-frozen patients all the worse for their contact. While on the other hand, I have known—and who has not?—men who were of such exuberance of vitality and kindliness that however humble their degrees the mere clasp of their hand and light in their eyes have left their patient in a more cheery and hopeful mood. Above all, no doctor has a right to be a pessimist. If you are conscious of that temperament you should fly the profession. A reasoned optimism is essential for a doctor. He must believe the best, and so he goes half-way to effecting it. We have known for all time that the cheery man was the healing man, but now in hypnotic suggestion we come upon the physical explanation of the fact. If you can convey the expectation of cure you have served your patient well. You need not go the lengths of a doctor I knew, who used to say to his neurotic and hysterical cases, 'Now, Miss So-and-So, you will take three doses of the medicine, and then watch the clock till it is quarter-past five, and at that instant all your troubles will disappear.' It is true that his prophecy was often fulfilled, and yet the method was perhaps a little crude for general use.

With a knowledge of medicine you will find that you bear with you a little private lantern which throws a light of its own. It illuminates many an incident which is dark to the

layman. In every transaction of the world, you are likely to find medical facts down at the root of it, influencing its origin and growth. I know few more interesting lines of thought than this, and there is a wide field for the writer who will explore the influences of medical facts upon social customs and upon historical incidents. To take an obvious example of what I mean, for centuries mankind beautified themselves by means of wigs. You go into any picture gallery and you see your bewigged ancestors, full wigs, and tie wigs, and bob wigs, staring arrogantly at your cropped modern pate. Whence came such a custom, unknown to antiquity and absurd in its nature? Medical, of course. A skin disease on the top of the head of Francis the First of France, which induced alopecia, or bald patches, compelled him to cover himself with artificial hair; his courtiers all followed suit, exactly as they all whispered when the same monarch got laryngitis; and so, the custom enduring after the true cause of it was passed, you find the explanation for all your tow-headed ancestors. It is a very typical instance of the influence of a medical fact upon social manners. But when you come out into the wider field of history, what an enormous and fascinating range of thought lies before you, one almost untouched by the lay historian, and seldom explored by the medical writer. The association of certain diseases with certain characters is an extraordinary problem. To take an example, I suppose there are few men who have influenced history more deeply than Julius Cæsar and Mahomet. They were both epileptics. Is not that a most remarkable fact? Many other great men, including Napoleon, St. Paul, and Alexander the Great, may be said to be under suspicion, but these two were undoubted. Julius Cæsar was, I believe, at all times of his life subject to fits, although it is on record that the open-air life which he led with the legions during the Gallic war had a very favourable influence upon his health. But to the end he was an epileptic. Then as to Mahomet, we know that he also had sudden trance-like fits, quite apart from his religious visions, so that even the most pious Mahomedan must admit them to have been symptoms of disease. Such conjunction of the highest human qualities with a humiliating disease has surely both its pathological and its moral interest. Pathologically, one might suppose that there is a limit to the point to which the keenness of the spirit can drive the body; that at last the strain tells, and they tear away from each other, like a racing engine which has got out of control. Morally, if the human race needed anything else to keep it humble, surely it could find it in the contemplation of the limitations of its own greatest men. I have mentioned Napoleon, and I would further adduce him as an example of the sidelights and fresh interests which a medical man can read into history. One can trace for many years, certainly from 1802, the inception of that disease which killed him at St. Helena in 1821. In 1802 Bourrienne said: 'I have often seen him at Malmaison lean against the right arm of his chair, and unbuttoning his coat and waistcoat exclaim, "What pain I feel!"' That was perhaps the first allusion to his stomachic and hepatic trouble; but from then onwards it continually appeared, like Banquo at the banquet. He could scatter the hosts of Europe and alter its kingdoms, but he was powerless against the mutinous cells of his own mucous membrane. Again and again he had attacks of lethargy, amounting almost to collapse, at moments when all his energy was most required. At the crisis of Waterloo he had such an attack, and sat his horse like a man dazed for hours of the action. Finally, the six years at St. Helena furnish a clinical study of gastric disease which was all explained in the historical post-mortem examination which disclosed cancer covering the whole wall of the stomach, and actually perforating it at the hepatic border. Napoleon's whole career was profoundly modified by his complaint. There have been many criticisms—not unnatural ones—of his petty, querulous, and undignified attitude during his captivity; but if his critics knew what it was to digest their food with an organ which had hardly a square inch of healthy tissue upon it they would perhaps take a more generous view of the conduct of Napoleon. For my own part, I think that his fortitude was never more shown than during those years—the best proof of which was, that his guardians had no notion how ill he was until within a few days of his actual death.

History abounds with examples of what I have called the romance of medicine—a grim romance, it is true, but a realistic and an absorbing one. Medicine takes you down to the deep springs of those actions which appear upon the surface. Look at the men, for example, who were the prime movers in the French Revolution. How far were their inhuman actions dependent upon their own complaints? They were a diseased company—a pathological museum. Was Marat's view of life tainted by his loathsome skin disease, for which he was taking hot baths when Charlotte Corday cut him off? Was the incorruptible but bilious Robespierre the victim of his own liver? A man whose veins are green in colour is likely to take a harsh view of life. Was Couthon's heart embittered by his disfigured limbs? These are the problems where medicine infringes upon history, and these are the illustrations of the philosophy which is only open to the medical thinker. How many times do the most important historical developments appear to depend upon small physical causes? There is, for example, the case of the Revocation of the Edict of Nantes. By this measure the whole history of France has been profoundly modified, because by that action there were driven forth the Huguenots, who were the most stable and Teutonic portion of the nation—I say Teutonic, because religion is a great test of race—and the result has been to destroy the balance of the nation and to leave France as brilliant as ever, but without a certain solidity which she possessed before. On the other hand, it reacted profoundly upon surrounding nations, giving us and others a fresh accession of the most valuable strain which has prospered greatly ever since. Now, how came Louis XIV., who had always held out upon this point, to give way at last to the pressure of Madame de Maintenon and his clerical advisers? The answer lay in one of his molar teeth. It is historical that he had for some months bad toothache, caries, abscess of the jaw, and finally a sinus which required operation; and it was at this time, when he was pathologically abnormal and irritable, that he took the step which has modified history. Great results may depend upon a king's jaw or a statesman's digestion. There is one thing which may be said of those terrible competitive examinations which are called Parliamentary elections, and which give us our rulers. No one who is not physically fit is ever likely to get through them."

Sir Arthur Conan Doyle then briefly sketched the empirical methods of medicine in the past and the consequent weakness in medical science which was due to vagueness of knowledge. Of the present generation he said it "has, as it seems to me, brought about a greater change in medical science than any century has done before. At last there is some attempt to make it exact instead of empirical. Great results have been obtained, and even greater ones have been promised for the future. We fought a hidden enemy. You have brought him out into the open. It is true that the microbic origin of zymotic disease was taught 30 years ago, but we could hardly hope at that time that so many of these minute organisms would be actually separated, and that we should be able to artificially cultivate these lowly vegetable growths with the same certainty as we grow watercress or sweet peas. This would indeed have seemed to us to be a most far-fetched chapter in the romance of medicine. In every literary or dramatic romance you will observe that from the time that the villain is unmasked he is innocuous. It is the undiscovered villain who is formidable. So it has been in this wonderful romance of medicine. All this work of late years has been in the direction of exposing the villain. When once this is done, be he micrococcus or microbe, and be his accomplice a mosquito or a rat-flea, the forces of law and order can be turned upon him, and he can be broken in to comply with that system which he has defied. The story of how these forces of evil were exposed, how one by one their machinations were traced, is, I think, one of the most wonderful and certainly one of the most eventful in science. It is one also which we, as Britons, can regard with a peculiar satisfaction, for our fellow-countrymen have been protagonists in the battle. That great line which honours British medicine since the days of Harvey has never had a more brilliant group than that which contains the names of Manson, Ross, Bruce, and Wright."

Then in language calculated to arrest the attention and excite the emulation of the student he told of the untiring patience of Sir Patrick Manson in his pursuit of the methods by which filaria was transferred from one human body to another, a good instance, he said, of the fact that knowledge and good work are never thrown away and often find their fruition in a manner never contemplated by the original

worker, for in this case the work of Sir Patrick Manson put Major Ronald Ross on the track of finding the methods of conveyance of malaria, with the result that life in Italy, Greece, Ismailia, the West Coast of Africa, the West Indies, and other places was being profoundly altered. Sir Conan Doyle then briefly alluded to the splendid work of Sir David Bruce in the discovery of the micrococcus of Maltese fever, and the proof that the milk of goats was the chief medium of infection, and he also showed how Sir Almroth Wright by his opsonic researches had supplemented the work of Koch in the fight against disease. He concluded:—

"Now I have spoken long enough. Let my last words be personal to yourselves. The great Abernethy, when he was asked to give such an opening address, and when he saw the lines of students before him, cried out, 'Good God, gentlemen! what is going to become of you all?' I think that under modern conditions one can say what will become of you all. You will find your work ready to your hand. Some will find their way into the great Services, some into the over-sea Empire, many into private practice. For all of you life will offer hard work. To few of you will it give wealth. But a competence will be ready for all, and with it that knowledge which no other profession can give to the same extent, that you are the friends of all, that all are better for your lives, that your ends are noble and humane. That universal goodwill without, and that assurance of good work within, are advantages which cannot be measured by any terms of money. You are the heirs to a profession which has always had higher ideals than the dollar. Those who have gone before you have held its reputation high. Unselfishness, fearlessness, humanity, self-effacement, professional honour—these are the proud qualities which medicine has ever demanded from her sons. They have lived up to them. It is for you youngsters to see that they shall not decline during the generation to come."

MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS ON "THE MEDICAL PROFESSION AND ITS ATTRIBUTES," DELIVERED BY WALTER S. NOWELL, M.R.C.S. ENG., L.R.C.P. LOND., L.D.S. R.C.S. ENG., DENTAL SURGEON TO THE HOSPITAL.

Lord GRENFELL, in the absence through illness of Prince Francis of Teck, presided over a large company who had assembled on the occasion of the presentation of the prizes by Lord Kitchener.

Lord KITCHENER, who had a great reception, pointed out the vast work which had been accomplished by the Army Medical Service and the Indian Medical Service, and insisted upon the necessity that the combatant branch should second the efforts of medical officers in the treatment of disease in times of peace as in times of war. He bore personal testimony to the vastly improved sanitary conditions of India and of Egypt as a result of the efforts of the medical officers of the two services, but regretted that there still remained in India vast sanitary evils which had to be combated. Making full allowance for the difficulties of dealing with 300 millions of natives, many of them blindly obedient to creed or cast and dwelling mostly in insanitary and overcrowded cities, Lord Kitchener still found that England had somewhat fallen behind other nations in the struggle for the prevention of disease by means of organised sanitary methods, and he appealed to his audience to do their best to remedy the situation.

Mr. NOWELL, after thanking Lord Kitchener for coming to present the prizes and expressing his appreciation of the honour he felt in having been invited to give the address, quoted the passage in which Robert Louis Stevenson refers to the physician as the "flower of our civilisation," and made some remarks on the antiquity of medicine, passing in review the influence on its character and practice of such men in turn as Hippocrates, Celsus, Galen, Paracelsus, Sir Thomas Browne, Harvey, John Hunter, and Jenner, and coming to the nineteenth century Sir Charles Bell, John Abercrombie, Sir Benjamin Brodie, Sir James Simpson, Lord Lister, Koch, Pasteur, Ross, and many more. Mr. Nowell continued:—

"Thus you will observe that not only is the profession of medicine ancient and honourable, but throughout the ages it has maintained, broadly speaking, a remarkable continuity of purpose in its aims, ambitions, methods and work. Its aim and ambition have been by scientifically studying Nature to discover the cause and origin of disease, and by putting such knowledge through the sieve of practical experience to render the tested residue available for preventive and curative treatment. Its method has been intelligently to observe and to reflect on the phenomena of life in health and in disease, verifying these by experience, experiment, and reasoning research, whilst our practical work or function, especially in the eyes of the public, has been, and is, to prevent and to eradicate disease, to heal the sick, and to relieve suffering. These seeds of purposeful energy have always borne good fruit. Throughout the ages the men who have in their day, and usually in a quiet unobtrusive way, added to the sum-total of medical knowledge, or upheld the dignity of the profession, or elevated it a notch or two up the social grade,—such men, I say, have not effected these things merely by profound medical learning, but also by blending into their characters methods of work, habits of life, and certain high ideals which may aptly be termed the 'professional attributes.' Professional work of any kind tends to narrow the mind. Most of us have noticed this in callings other than our own, particularly perhaps in that of the schoolmaster, but the tendency exists with us also; least I think in the case of the busy, cultivated general practitioner, most in the individual who, like myself, has narrowed down his field of practice and possibly also his field of mental vision to some special branch. Therefore, you should cultivate those good habits you already possess, and gradually endeavour to assimilate such characteristics as may, and indeed must, from time to time favourably impress you in others. But perhaps the 'wisest habit of all is the habit of care in the formation of good habits,' inasmuch as it is often harder to unlearn than to learn, and to uproot a bad habit is sometimes painful and difficult. In forming 'methods of work' fix on your object, but do not allow your thoughts to wander and worry over future difficulties, try rather to concentrate your attention on the day's work. To be successful in your work you must be self-reliant, thorough, accurate, methodical, and above all you must be interested in it. Now if you become interested in medical work you are bound in natural sequence to become interested in human nature and to realise the truth of that line in Terence: 'Nihil humanum a me alienum est puto.' In this spirit you will acquire the gentle art of gleaning knowledge from everyone you meet, whether lecturers, teachers, nurses, fellow students, or patients, until you can truly say, like Tennyson's Ulysses, 'I am a part of all that I have met.'

With regard to 'habits of life' I would merely say cultivate regularity and punctuality, avoid extremes, and pursue the '*το μεσον*'—that is, be reasonable in all things. If you would attain lasting happiness you must constantly endeavour to maintain physical as well as mental fitness.

Fellow students of medicine, allow me to wish all of you happiness and success in this school, in this hospital, and in your future careers; and when your working days are over may you be able to say, as Richter did, 'I have made as much of myself as could be made of the stuff, and no man should require more.'"

ST. GEORGE'S HOSPITAL.

INTRODUCTORY ADDRESS ON "PRIZES AND PERFORMANCES," DELIVERED BY S. SQUIRE SPRIGGE, M.D. CANTAB.

AFTER remarking on the double occasion which had brought together his audience—viz., the award of prizes and scholarships to the successful students of the school in the past academic year, and the inauguration of the new session—Dr. SPRIGGE went on to discuss the relation between prize-winners and their after performances. He alluded to the fact that different persons, or the same person on different occasions, viewed the relation between winning of prizes and the winning of success in after life in diametrically opposite manners. "I am certain," he said, "many of us have spoken as though we believed that prize-men are apt not to stay the course. This is when we hear of the insignificant future which some brilliant student has made for himself—perhaps when we hear of the first mathematical scholar in our batch at school as an under-master in a second-rate seminary or notice the best classic of our year at college dozing away a valueless existence in front of a club fire, or using his knowledge of the classical dictionary in guessing acrostics." Yet most people, in congratulating a prize-winner, protest that nowadays in a world of stress and competition, there is nothing

like making a good start. The two views, he said, indicated a considerable diversity of estimate with regard to the merits of the system of awarding prizes, exhibitions, and scholarships in the course of the educational career, if the same people could be found uttering such opposite opinions, and not only uttering them but sometimes acting upon them. But, the lecturer pointed out, whichever view is taken no one ever suggests that education can be carried on to a practical end in any other way. Verbally men are found willing to sacrifice a lightly held conviction as to the value of prizes and examinations to a desire to be agreeable, but even then they endorse the principle of examinations and rewards, alluding to them as a growing abuse good to grumble at. This he considered to be really an admission that there is no way of ascertaining whether students are up to a certain standard save by examinations, and that there is at least no surer way of stimulating the work of a group of students than by appealing to an honourable as well as to an inevitable spirit of rivalry. That thinking men are divided into two distinct camps on the question of the value of prizes and the necessity of their inevitable accompaniment—examinations—Dr. Sprigge found due to the usual fact where sensible people disagree, viz., that both parties are not talking about the same thing. "Those," he said, "who cry out most clearly and persistently against the need of examinations and the reliability of prizes as a gauge of future success are regarding education as a thing which begins at a certain time and ends at a certain time—something like measles which you get young, and get done with. If this view of education be taken, it is easy not only to show that success in examinations is no certain gauge of success in life, but also that the whole system of examinations and prizes is wrong. But medical education does not happen to end with registration, or qualification, with the obtaining of a commission, a diploma, or a degree, and there is no professional curriculum in which this can be seen more clearly than in the medical curriculum, in relation to which it is stark staleness to say that education never ceases and that the longer we practise our calling the more we have the opportunity of learning, of testing that learning, and of obtaining its rewards. Modern conceptions of medicine are such that all men in whatever walk of life they are practising see that their life is one long education, and that all they have learned in the past may be regarded to some extent as an introduction to all that they hope to learn in the future."

Regarding education in this comprehensive way, Dr. Sprigge argued that the two contrary views as to the value of examinations and prizes became at once reconcilable. Prizes and examinations had their necessary place in the early educational scheme because they were a necessary part of a determination, resolved on by those responsible for the State scheme of medical education, that no one should enter the ranks of the profession who is not so far educated that he can take full advantage for his own benefit, and notably for the public benefit, of the greater and more comprehensive education which is to proceed during the rest of his life-time. Examinations, he said, were a means to this end and no more; prizes were an incentive to this end and no more; at which point the speaker introduced a protest against the multiplicity of the examinations and their intricacy which had of late marked the medical student's curriculum. "The system of examination," he said, "is too hardly worked, because of the unfortunate feeling that all the modern developments of medical science, general and special, laboratorial and clinical, ought to be represented in the examination papers. The mesh of the net spread by the examiners has become too delicate; they catch in their elaborate toils too many." But he warned his hearers against regarding knowledge pursued for its own sake and with no materialistic proposal as of little account, finding that the subtlest classic and the most transcendental mathematician had his place in the scheme of education in the broad humanities, just as the elaborate biochemist and statistical eugenist had his in medicine. Their knowledge was required as a reinforcement of ordinary learning, as a proof of its basis, and as an index to the direction of its expansion. Therefore, it was unfortunate that the highest ranges of philosophical research seldom brought their due return in money, and their devotees were forced largely to depend for their reward upon the sweetness of their labours, the keen and splendid delight in the exposition of the rarest wisdom. "In the commercial world," said Dr. Sprigge, "the creation of interests is too often intended merely to extinguish other interests, but in the world of medicine the gains of one man are used for the good of all, and the supreme type of this unselfishness was the worker in the highest planes of research. But in this country those engaged in such work are far away from the pleasures and lures of tangible prizes. Unless the philosopher can by his learning show the capitalist or the shareholders how to transmute baser material into gold, it's little enough gold that he will get in return for his toil. And this is not because the exponent of the highest wisdom is necessarily a visionary, but because the application of his researches is never quickly obvious to a nation that is still in the ancient attitude regarding education—a nation which still believes that education is something like a disease of childhood. To such the man who continues in the laboratory or the library appears to be a sort of permanent invalid removed by a malady of interesting duration from connexion with the real problems of life." He claimed it as one of the greatest glories of modern medicine that it had taught the modern generation of its workers a broader view, for the whole story of pathological progress, which has been so striking during the last 20 years, might be summed up in the statement that scientific research of the highest and broadest kind, in physics and chemistry—in which was included physiology—had been made to play a part in practical medicine, therapeutical and preventive.

The lecturer concluded as follows: "Although the profession of medicine is showing the way by which in its work-a-day proceedings the finest flowers of its philosophy can be gathered and used, the fact remains that prizes, material prizes, come no more in medicine than in other walks of life to the actual exponents of that philosophy. The simple way in which this great wrong could be in fact set right would be by some wider endowment of teaching. Into the hands of the leaders of our thought falls the duty of teaching our students, but in London in particular the duty is largely discharged as a gratuitous one. The shortsightedness and false economy of encouraging students freely with exhibitions and scholarships while making scanty provision for those who teach them is simply an exhibition of the old and narrow view of education. The successful student is rewarded with prizes at the end of his first lap; let him rejoice and be glad in them, for assuredly his strictly academic career will bring him few more emoluments. It is an absurdly wrong policy which leads wealthy and generous persons so much more frequently to found scholarships for the students than lectureships, readerships, fellowships, and professorial chairs for their teachers. Both are wanted; but the needs of the instructed always appear in this country to appeal much more powerfully to donors than the needs of the instructors. What right have we to expect that the highly-endowed student will receive adequate instruction if we fail to endow his masters? The course of education is a long one. Those who once were taught become the teachers; they have reason to expect some continuance of the encouragement which they received at the early stages of the race."

LONDON SCHOOL OF MEDICINE FOR WOMEN.

INTRODUCTORY ADDRESS BY E. W. ROUGHTON, B.S., M.D. LOND., F.R.C.S. ENG., SURGEON TO THE ROYAL FREE HOSPITAL.

Mrs. GARRETT ANDERSON, M.D., President of the school, in opening the proceedings, mentioned that the entry this year was the largest they had ever had—viz., 31—and that of these 30 were starting with the definite intention of taking the M.D. degree of the University of London.

The subject upon which Mr. ROUGHTON spoke was "Woman's Sphere in Medicine." After offering a cordial welcome to the new students, he gave an outline of the course of study, comparing the human body to a piece of mechanism which, though prone to wear out and to get out of order, possessed to a wonderful extent the power of repairing itself and withstanding the influence of injurious surroundings. He then said: The distinguishing feature of this school is that it is for women students and for women only. It is, therefore, appropriate that I should say something about medicine as a profession for women and about the suitability of women for medical work. Of late one has heard so much about the equality of the sexes that one can hardly help thinking that in the minds of many people sex distinction is chiefly a matter of costume and political

disability. For such, medicine is just one of the numerous occupations which may be taken up equally well by male or female. On the other hand, there are still some old-fashioned people who believe that woman's place is in the home and that no occupations outside the domestic sphere are suitable for her. They are apt to forget that owing to the preponderance of the female sex there are not enough husbands to go round; moreover, there is no reason why a woman should get married if she prefers to remain single and earn her own living. Sixty years ago it may have been necessary for Bob Sawyer to engage in pugilism, cock fighting, wrenching off door knockers, and such like pastimes in order to make himself sufficiently brutal to be able to perform a major operation whilst the patient was writhing and shrieking in agony. Such a profession was scarcely suitable for the early Victorian young woman, whose chief occupation seems to have been keeping her hands white and making her mouth a pretty shape by diligently repeating the words pears, prunes, and prisms. The invention of anæsthetics and antiseptics has made surgery a gentle art which can be practised by the most tender-hearted man or woman. Over and above the fact that medicine is a suitable profession for women, there is a very cogent reason why there should be a female section of the profession. I suppose that everybody (including even the opponents of medical women) would agree that it is desirable that women should be attended by persons of their own sex, if only one could be sure that the female practitioner was as efficient and reliable as the male. The need for medical women in countries where men are not allowed to attend the female sex is of course obvious. Custom accounts for a good deal, and I feel sure that the present custom of women being attended by men has only grown up through sheer necessity, and that when in the course of time there is a plentiful supply of medical women, people will wonder how their grandmothers could have submitted to the services of the male obstetrician or gynæcologist. Although there are many ailments where the sex question hardly comes in, I feel strongly that the more the sexes are separated in medical matters the better. For my own part, I should be glad to see a complete division of male from female in hospital work. The example set by the New Hospital for Women is an excellent one. I should like to see the male counterpart—viz., a hospital for men with male officers and nurses; but I very much doubt whether a sufficient number of men would ever be found with the necessary qualities for making good nurses; but that question, though an interesting one, is outside the scope of this address. I also think that mixed classes of medical students are undesirable, and I congratulate you on having joined a school where there are women students only. I would go even further and would say that it is desirable that your teachers should all be women; at present such perfection is not possible, but it will come some day.

Granting, then, that medicine is a suitable profession for women, the next consideration is the suitability of women for the profession. Many women will no doubt be inclined to dismiss the question by saying confidently, "Of course they are suitable, just the same as men." I crave your indulgence for a few minutes in order to discuss this question; for although I shall arrive at very nearly the same conclusion I may be able to lay before you some propositions attention to which may tend to increase your suitability for the profession you are aspiring to enter. Firstly, let me remind you that there are radical differences between the sexes, and that these differences are not comprised by what are usually known as the primary sexual characters; there are other differences between male and female which are called secondary sexual characters; some of these are self-evident and therefore well known; for instance, the greater muscular development of the male, the deeper voice, the beard, and so on. These obvious characters have little or no bearing on the practice of medicine. There are other more subtle differences between the sexes which are sometimes known as tertiary sexual characters, and which I think are more important in deciding the suitability of the sex for the work in question. These characters are especially worthy of attention because they are not so radical and unalterable as the more obvious secondary characters; they are to a large extent capable of being influenced by education and by discipline. In order to understand them it is necessary to remember that in primitive races the different parts taken in the reproduction of children by the two sexes has made the occupations of man and of woman essentially different. Of necessity the woman has been obliged to stay at home and nurse the babes, whilst the man has had to go out and procure food by hunting and fishing; having got the food he often has to fight with his neighbours to protect his belongings. Male and female have therefore been thrown amongst different surroundings, and in obedience to the law that organisms must adapt themselves to their environment have developed different qualities. Thus the male has developed muscular strength, courage, and cunning in the chase, whilst the female who would rear her children successfully could only do so by unselfishness, solicitude, and sympathy; as an Australian Kurnai is reported to have said: "A man hunts, spears fish, fights, and sits about; the rest is woman's work." One of the most obvious results of this division of labour is the woman's sense of dependence upon the man. "She has so long looked to the man as protector, breadwinner, almost as owner, as the one to initiate, to lead, to control, that her capacities have been dwarfed in these directions; her powers of self-reliance, origination, invention have found no outlet and have in consequence remained quiescent or at least have but feebly developed, her mental growth being rather in the direction of such qualities as are comprised under what has, in consequence, come to be called womanly sweetness, or more briefly, womanliness."[1] Evidently these qualities are more suitable for a nurse than for a doctor; if all women were alike in this sense of dependence upon men it is fairly certain that there would be no women doctors. But the history of the woman's medical movement shows clearly that there are many women in whom the qualities of independence and self-reliance are very fully developed. The mere fact of a young woman desiring to enter the medical profession shows that she possesses these qualities in some degree, but it will be well for you to remember all through your career that there is a tendency to revert to the primordial type; therefore take every opportunity of increasing your self-reliance by doing things for yourselves as much as possible whilst you still have your teachers to fall back upon in case of failure. Very lucky indeed are those young women who will have an opportunity of strengthening themselves in this respect by holding a resident post at the Royal Free Hospital.

Women appear to adapt themselves mentally to varying surroundings more readily than men; this peculiarity has been attributed to the necessity she has been under of adapting herself to man, always her superior in strength, and always, therefore, possessing the authority which strength confers. This mental adaptability shows itself chiefly in the greater tactfulness which the woman has no doubt acquired through the moulding influence of the stronger sex; for, finding herself opposed to brute force, and being no match for her husband in this respect, she has had to depend on other resources, defensive and offensive. Closely allied to her tactfulness is another quality which is not so commendable. It is her capacity for dissembling. There are many reasons, which I need not enter into, which account for the undoubted fact that women are more clever at deception than men. There can be no doubt that in the practice of medicine it is sometimes necessary to deceive a patient in her own interest, but as a general rule I strongly advise you to say what you mean and mean what you say. Although this sounds quite simple and easy, I can assure you that it is really very difficult and requires a great deal of practice. You will find this out when as dressers or clerks you write records of the cases in the wards. You will find it difficult enough to record your own observations accurately; and when you come to writing down the patient's account of his symptoms and history, and comparing it with the answers he gives to the physician or surgeon at his afternoon visit you will realise the truth of what I say. Another result of the primordial differences in the male and female environments is that the woman's mind retains more of its child-like characters than does that of the man. All through the animal kingdom the adult female is more like the young of either sex than the adult male, and this is so in the human species. Up to the time of puberty the development of the two sexes runs

[1] Differences in the Nervous Organisation of Man and Woman, by Harry Campbell, M.D.

fairly parallel, although from the earliest age there is a foreshadowing of essentially masculine and feminine traits. At puberty the unlikeness of the two sexes suddenly increases, the male departing much more than the female from the previous childlike characters. Thus it comes to pass that some women are inclined to be weak-willed, acting upon the impulse of the moment without due reflection on ulterior consequences; some, again, are highly emotional, passing rapidly from one phase of feeling to another, from tears to laughter, from frowns to smiles; others are wanting in control, wayward and petulant. These childish women are no use at all in the medical profession; but there are others who possess the childlike qualities of sincerity, modesty, simplicity, honesty, and trustfulness; such possessions should be carefully preserved lest in the development of the higher faculties they be crowded out.

Coming now to the more purely intellectual powers, there are some interesting points to be noted. There is no doubt that in European races the absolute weight of the brain in men is considerably greater than in women, but when we allow for the greater size of the male and compare the proportion of brain weight to body weight, we find that women's brains are at least as large as men's, and, indeed, often a trifle larger. It is, therefore, not surprising that our students do just as well as, if not a little better than, the men students presenting themselves for the London University examinations. You must not, however, be unduly puffed up at your success in examinations; allowance must be made for the marked precocity of the female brain in childhood and adolescence. Girls between the ages of 4 and 7 have already gained 92 per cent. of their final brain weight, whilst boys of the same age have only reached 83 per cent. The girl's brain grows but little after the age of 7, and has practically ceased to grow about the age of 20, whereas the man's brain does not reach its maximum size until the age of 30. It is not surprising, therefore, that girls are often intellectually ahead of boys of the same age; it may be fairly assumed that girls of 16 or 17 have arrived at the same stage of mental evolution as young men of 21 or 22. It is probable that there is very little difference between the intellectual capacity of the average man and the average woman; the boasted superiority of man only shows itself when we pass into the region of genius. Genius of the highest order is almost limited to the male sex, and this is in harmony with the well-known law—viz., that natural variations are more common and pronounced in the male. A genius may be regarded as an extreme natural variation—in a sense an abnormality. In harmony with this view is the fact that the opposite mental type—the idiot—is much more frequently met with amongst boys than girls. In the matter of rapidity of perception the advantage is distinctly with the female sex; thus it is by no means uncommon for a woman to be able to take in another woman's costume at a single glance, and to do it so thoroughly that she is able to give a minute description of it to a friend. Such powers brought to bear upon the clinical aspect of a difficult case cannot fail to be of the greatest use. In selecting things for various purposes there is a marked difference between the sexes. As a general rule a man selects a thing because it is useful, whilst a woman chooses an article because it is pretty, or because it conforms to some artificial standard which happens at the time to be in vogue. I have never been able to find out why a woman usually prefers a delicately sharpened chisel to a screwdriver for turning a screw or for forcing a packing-case open; but I am inclined to think it is due to lack of education in such matters. The problem of the screw is also a difficult one to decide, but as I have so often observed a woman attempt to turn a screw the wrong way before turning it the right way, I am inclined to think that the peculiarity must rest on some essentially sexual basis. Women do not, as a rule, seem to be so handy as men in looking after pieces of mechanism and in keeping instruments in order. They have a dislike for oil and a tendency to administer a violent bang to anything that will not work. This, again, may be to a large extent due to the fact that girlhood has nothing to do with carpentering or any other form of handicraft except dressing dolls. In my operative surgery class I usually have some preliminary sawing of pieces of wood before we proceed to the amputations.

There are many other points of difference between the sexes which I could tell you about, but it would take up too much time. I think I have said enough to convince you that man and woman are very different persons, and that in some respects, perhaps, man is at present more suited for medical work than woman, but that these differences are not all of them essential, but are capable of being overcome by education and assiduous practice. There are many men and many women who are quite unfit for the practice of medicine, and no doubt there are fewer women than men who have the necessary qualities. Nevertheless, when I compare the young women of to-day with the young women of Dickens or Thackeray I feel confident that there will always be a sufficient and a steadily increasing number of women taking up medicine.

Just as there are differences between the medical man and the medical woman, so there must be differences in the kind of work they are most suited for. For many years to come men will continue to attend both sexes as they have done hitherto, but *you* must limit your activities to your own sex and to young children. I do not know any medical woman who professes to treat allcomers, but if there is such a person I hold her to be an abomination. More especially will you devote yourselves to the diseases peculiar to women, for they are indeed the justification for your existence. Obstetrics, of course, is a subject in which our students ought to shine. Any student from this school who failed to satisfy the examiners in obstetrics and gynæcology ought to be heavily fined. Many of you, of course, will eventually go to India and engage in Zenana work, but there is plenty of work in this country for those who wish to stay at home. There are good posts to be had under the county councils and other public bodies. I do not mean that they are very good from the point of view of remuneration, but the work required is admirably suited for the average medical woman. Although it is responsible work, it is mainly of a routine nature, and is not likely to unduly tax the woman's self-reliance by suddenly calling upon her to assume responsibility of the first magnitude. The teaching of elementary hygiene, especially that part of it concerning the home and the care of young children, is essentially woman's work. You must not be downhearted if your teaching is spurned by some woman who will boast of having had twelve children and having buried nine of them; you will not find it wise to inquire after the odd three, as it often happens that one is a cripple, another a lunatic, and the third is "doing time." There are many valuable resident posts in hospitals for women and children, in sanatoriums, infirmaries, asylums, &c., scattered all over the country. Although valuable from the point of view of experience, they are mostly of a temporary nature and do not therefore offer much opportunity of earning a livelihood. Many women are now established in general practice in most of the large towns in England, and I understand that all of them are earning a living and some of them are doing very well indeed. I do not think all medical women are suited for general practice. The successful general practitioner must be able to work hard all day and a large part of the night year in and year out; he (or she) must be able to dispense with regular meals, a full night's rest, and an annual holiday. He must always be ready to listen to anybody's tale of woe in such a way as to give the patient the impression that his is the only interesting case in the world; he must never be impatient or lose his temper, even when after driving several miles on a cold night he is told he is not wanted. He must be capable of carrying any amount of responsibility on his shoulders, and of giving people the impression that he knows a good deal about his work. At the present time the majority of women employ male doctors because, having little or no confidence in themselves, they find it difficult to place any in their medical sisters; if, therefore, you have any doubt about being able to do all the things I have just mentioned you had better think twice before putting up a brass plate. As time goes on the sex will become better educated and there will be room for more and more women practitioners. The number of women suitable for the higher branches of professional work is necessarily small, though not smaller in proportion than in the opposite sex. Major surgery is only for the few, and I advise you not to attempt it unless you have confidence in yourself, your apparatus, and your assistants. That there are women whose operative work is of the highest excellence is proved by the statistics

of the New Hospital, which I believe are as good as those of any other hospital, special or general.

I have now occupied your attention long enough, and it only remains for me to wish you much happiness in the career you are about to embark on. My sincere hope is that in after-life you will always find pleasure in remembering the days when you were students at the London School of Medicine for Women.

MEDICAL DEPARTMENT, UNIVERSITY OF MANCHESTER.

INTRODUCTORY ADDRESS ON "THE EVOLUTION OF SURGERY," DELIVERED BY WILLIAM THORBURN, F.R.C.S. ENG., PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY.

AFTER affectionate references to Mr. F. A. Southam, who after 30 years' service has retired from the active staff of the infirmary, and to the late John Edward Platt, cut off by early death, Professor THORBURN recalled to their memory also John Dewhurst Milne, who, though not a member of the profession or of the University, had done so much for the welfare of their school. They were not, however, concerned with their personal losses so much as with their gains in the art of surgery. It would be easy by continued quotation from older text-books to show that the changes which they had seen with their own eyes and practised with their own hands had implied an evolution in surgery not less wonderful than the development of rapid locomotion, distant communication, and electrical science. He had made an effort to estimate what the gain had been in saving of life, limb, and suffering in their own infirmary in 25 years. Their death-rate from all causes after operation had fallen from 10·5 to 8·5 per cent., and they now operated upon nearly three-fourths as against one-fourth of all patients in the surgical wards. Whereas in 1883, 20 per cent. of deaths after operation were due to infective conditions, they could not now attribute more than 1 per cent. to such causes. Still more striking evidence of improvement in surgery was furnished by the class of operation now undertaken as a matter of routine which formerly was approached with fear and trembling. This great surgical advance owed itself unquestionably to two great fundamental discoveries—anæsthesia and asepsis. To-day they knew that the injury done by the knife was limited to the track of the knife itself, and that it would be repaired with a rapidity so great that after a few hours the most extensive dissections would have left no obvious trace, and it was to this fact above all others that they owed the comparatively recent extension of surgical dissection. There were a few tracts in the brain and spinal cord which a surgeon must not divide; there were a few—a very few—great blood-vessels which he must not cut, but with these reservations he found no barrier to his work. He could safely open, divide, and restore the great canals and ducts of the body and freely expose all its cavities and work in their interior with calm and confidence. He was not limited to a partial and imperfect view, but could freely reveal the parts he had to attack. The perfection of asepsis had so altered surgical methods that the greatest advances in the mechanical art of surgery in recent days had been due to a freedom of action and an exposure of the field of operation which were formerly incredible. Following this accuracy of dissection surgeons could take a further step which had also greatly assisted the evolution of the art. They now obtained a complete view of the effects of disease and diseased areas which their predecessors did not possess and dared not seek, and in this way modern surgical operations had taught them much of the real nature of disease. They might smile to-day at Aristotle's view that the brain was an organ destined to cool the heart, and that the latter was the organ of the mind, and find it hard to believe that there could be rational therapeutics before Harvey discovered the circulation of the blood, but the knowledge of many diseases with which surgery dealt daily was almost as much a revelation to the present generation as were the fundamental facts of physiology to a former day. The acquisition of the knowledge of diseased processes during life had altered the whole mental attitude and produced a clearer conception of the objects of surgery and marked a further stage in its evolution. Again, the extension of operative treatment had demanded and obtained an accuracy of diagnosis which was formerly not required. Five-and-twenty years ago if a man had a tumour of the brain or spinal cord it was of no practical importance where it lay or what it was. But the moment that surgery could undertake to remove some of these tumours, and thus to cure the patient, it became absolutely essential to know their exact size and position, and as far as possible their shape and consistency. A quarter of a century ago nearly all diseases of the abdomen were fatal; death was assigned to peritonitis, a general expression for many conditions which were not distinguished because the distinction was of no practical importance. The extension of mechanical technique had not only taught them pathology, it had also made them learn diagnostic medicine. Thus, then, the lines of advance after the elimination of pain and wound infection had been mainly the free exposure of diseased parts, the fuller knowledge gained thereby, and the greater necessity for prompt recognition of the early stages of disease. Each factor had reacted upon the others. Each step had called for the next and had made the next more easy; as quickly as the trail was made it was trodden by many feet, and in a very few years the jungle had become a network of solid roads from which again new byways were opening out. Lastly, much had been gained during these past years by the education of the public, by the appreciation by them as well as the profession of the necessity for promptitude. Not many years ago the patient "submitted to operation." To-day it was often more difficult for the surgeon to discourage the useless than to urge the necessary operation.

In 1876 Lawson Tait first removed some stones from the gall-bladder, and in 1909 Mayo Robson had collected 3000 of such operations performed by three surgeons alone, and with a mortality of less than 2 per cent. Twenty years ago the operation of gastro-enterostomy was introduced to surgery; it was now one of the commonest of remedial measures, and many thousands had been rescued by it from the slow martyrdom of so-called dyspepsia. In 1896 an Italian surgeon, Farina, made the first attempt to suture a wound of the heart itself, and in 1909 Vaughan collected 150 cases, with 35 per cent. saved from certain death. Still more recently they had seen successful operations for diseases of the heart, and an ingenious device by which it was possible to open the chest with the surrounding atmospheric pressure reduced to that in the bronchial tubes and operate upon the lungs and pleura. Operative surgery had not reached finality 30 years ago, and we might look to the future for an evolution not less wonderful than that of the past. But there were few gains which carried no losses in their train. There was perhaps a tendency to operate too readily and without due care for preliminary diagnosis. The very safety of surgery tended to diminish the sense of responsibility with which operations were undertaken. A closely allied danger was that of extreme specialism, which was another term for limitation of thought. Although inevitable it was none the less a misfortune of modern surgery. It tended to narrow the view and to obscure the human being in the consideration of each surgeon's favourite corner of his frame, to lead to the localisation of all ills in that corner, and to encourage operation upon that corner when it would have been wiser to adopt other measures.

Professor Thorburn concluded: "Let us not lose sight of the fact that, after all, the greatest surgeon is the greatest healer and not necessarily the most dextrous operator. And we may humble a little our pride in our art when we consider that it is, after all, an imperfect means towards one great end—the elimination of disease. Great as have been its triumphs and greater still as we may hope to make them, the greatest triumph will be when a fuller knowledge of the causes of disease, a more perfect development of preventive medicine, a higher evolution of social law, and a nobler gift of individual self-control shall finally eliminate or shall truly cure those human ills with which in our imperfect knowledge we still deal so crudely. Doubtless, gentlemen, it is too much to hope for the realisation of such a dream in the lifetime of any who are here to-day, but it is not too much to expect and trust that you who are now devoting yourselves to the great study of medicine may hereafter play a worthy part not only in advancing the art of surgery, but also in replacing that art by the still more perfect methods which it is our duty to seek and to which ultimately we may attain."

ON THE MEANING OF THE AUDIBLE SIGNS IN MITRAL STENOSIS.[1]

BY ALEXANDER MORISON, M.D. EDIN., F.R.C.P. LOND. AND EDIN.,

SENIOR PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL.

ON the last occasion on which I read a paper before the Æsculapian Society I endeavoured to show how much may at times be learned from what I called the *vivisection of disease*[2] in a single case, which has been carefully watched during life and examined after death. I propose on this occasion to consider the light which may at times be thrown on debatable questions by the clinical examination of a single case of heart disease in various phases of its action.

There are few diseases of the heart which have been more studied than mitral stenosis, and it still presents features the interpretation of which is subject of dispute. It is a common experience to find different phases, accidents, or effects of a given cardiac lesion presented by different cases. While these may be pieced together and general conclusions drawn, the convincing value of a clinical patchwork is not so great as that of the consecutive observation of a series of interdependent phenomena in the same case. A unity dissolved and re-united before our eyes or in our ears is more illuminating to the understanding than the composition of fragments into a whole when the phenomena of life are concerned. In the case I am about to relate this dissolution and combination of the signs of mitral stenosis occurred with unusual clearness.

The patient, a gardener, 29 years of age, was admitted under my care at the Great Northern Central Hospital on May 13th, 1909, suffering from breathlessness on any exertion. A week previously he considered himself in good health, though unemployed, and having only taken a cup of tea, walked 40 miles in search of work, which he did not find. On his return he felt tired but not otherwise ill, partook of a good meal, and went to bed. During the night he complained of sore throat, evidently due to a tonsillitis which later suppurated and burst in three days, when he felt relieved. While sitting quietly reading during the same afternoon he was seized with palpitation of the heart and pain in the lower portion of the left side of the chest. The conditions continued more or less until his admission to hospital. The patient stated that he had had a similar attack two years previously, but was quite unaware that his heart was affected, and stated that he had never suffered either from rheumatic or scarlet fever.

The patient was noted on admission to be a well-developed man, who did not look "very ill," lay quietly on his back, evinced no dyspnœa, but had some cyanosis of his lips and ears. The pupils were "rather dilated." The respiratory movements are noted to have been "poor" and their rate 22 in the minute. Posteriorly there were a few crepitations at both bases, but no friction sounds. The cardiac impulse was "very diffuse," and the apex beat, which was in the fifth space one inch outside the nipple line, was characterised as "forcible" by the observer. The impulse was not forcible elsewhere. The first and second heart sounds resembled one another closely; the heart-rate was 180 to 192 in the minute, the rhythm regular, and there was no bruit. The radial pulse was scarcely perceptible, and the blood pressure measured 95 mm. of mercury by the Riva-Rocci instrument. There was no distension of the abdomen, which was tense and rigid. The liver dulness extended from the seventh rib to "two fingers' breadth below the costal margin." Other abdominal organs could not be palpated on account of the rigidity of the abdominal walls. The urine had a specific gravity of 1022, showed a cloud of albumin, and contained a heavy deposit of urates. There was no œdema of the legs, which exhibited severe cramps on any attempt to flex them at the knees. For these notes of the condition of the patient on admission I am indebted to my house physician, Dr. A. E. Gow. Sphygmograms were also taken. (Figs. 1 and 2.)

On the next day (May 14th) the tachycardia continued, but the pulse was noted as being stronger at the wrist and easily felt there. The patient vomited after all food. On the 15th the pulse-rate had dropped to 60, vomiting had ceased, and the following note was made: Apex-beat fifth space, 4½ inches from mid-sternum; impulse visible and palpable; area of cardiac dulness 4½ × 5 inches. Sounds: at apex, clear first sound, followed by two sounds, the first short, the second long, which has the character of a "murmur." (By this was meant that the second of these sounds was a tone-sound, but blunted as though by an intermingled murmur vibration.) These apical sounds might be "graphically represented thus ——⌣——·····. At base, short reduplication of second sound in pulmonary (arterial) area. Aortic sounds normal. No abnormal pulsation in the neck. No thrill anywhere." On the 17th the physical signs at the apex and base of the heart were unchanged. On the 20th the pulse-rate was 64 and the rhythm regular. The second sound was reduplicated at the base. At the apex there were still three sounds, the first longer than before, the second as short as before, the third shorter than before. They might be represented thus, ——⌣——·····. On the 23rd the pulse-rate was "normal" and there was now present a typical *crescendo* presystolic bruit. On the 24th the pulse-rate was 72, the presystolic crescendo bruit was present, and sphygmograms were taken (Figs. 5 and 6). On the 31st the pulse-rate with the patient standing was 78, the bruit typically presystolic, the cardiac second sound slightly reduplicated at the base, and the rhythm of the heart regular. In the recumbent position these signs were the same. The blood pressure measured 135 mm. of mercury.

On June 4th the patient developed a left tonsillitis, with moderate temperature, and on the 7th the pulse-rate was 78 to 86 at the wrist and 114 at the heart, but he still exhibited a well-marked "rolling" presystolic murmur, as it is termed in the notes. On the 10th at 2.30 P.M. the heart again broke into a tachycardia of 168, with regular rhythm and no bruit. There was no subjective distress and occasionally "slight suspicion of systolic impurity at the apex." At 2.40 P.M. on the same day—that is ten minutes after the commencement of the attack—Dr. Gow notes that the pulse- and heart-rate were 84 and regular, there was triple rhythm at the apex, and a "diastolic bruit." The patient left the hospital with restored cardiac action and a crescendo presystolic bruit on June 11th, 1909—that is, about a month after admission.

The chief points in this case on which I wish to offer a few remarks are: (1) the prodromata and apparent causes of the disturbed cardiac action, regular and irregular; (2) the character and meaning of the apical and basic signs present, including the crescendo murmur; and (3) the arrhythmical action of the heart.

This case exemplifies a common clinical experience—namely, that of the existence of unsuspected valvular disease. It is not very material to inquire with what relative frequency this or that valve is the subject of unsuspected disease. My own experience is that mitral stenosis is very often overlooked, and likewise that, in inquiring into the previous history of such cases, one often fails to find a record of the most common causes of endocarditis, such as rheumatic and scarlet fever and the history of other septicæmias. Even chorea, which is at times admitted under these circumstances to have affected a patient in early life, may find no record. The patient has, in fact, regarded him or herself as perfectly healthy until some incident, it may be of exertion or emotion or of both combined, has induced an acute cardiac failure with such suddenness as even to give rise to the belief, on the part of medical observers, that a valve has been freshly ruptured. The "rupture," however, proves in most such cases to have been one not of cardiac structure but of so-called cardiac "compensation." At other times the sudden disorder of cardiac action may follow the occurrence of some debilitating general disorder.

In the present instance, a well-made man, unemployed but employable, is exhausted, and doubtless depressed, by a long and fruitless search for work, takes insufficient food for a fatiguing journey, develops a suppurative tonsillitis, and when apparently convalescent suddenly finds himself overwhelmed by cardiac palpitation. After recovery a short recurrence of tonsillitis with some temperature induces an arrhythmical action, which suddenly blazes into a short and sharp tachycardia, which subsides as suddenly as it arose.

These sudden explosions of erratic action and as sudden resumptions of functional quietude and regularity would until comparatively recently have been regarded as mainly

[1] A paper read before the Æsculapian Society of London.
[2] THE LANCET, Jan. 9th, 1909.

of neural origin. There are those, however, who now favour more largely one or other form of disordered action in the "essential properties" of visceral muscle as the source of such changes in cardiac action. The latest expression of myogenic thought in explanation of such phenomena as we have been considering is that a condition termed by Lewis fibrillation of the auricle is the cause of irregularity of the heart—a condition very frequently met with in cases of mitral stenosis.

It would be out of place on the present occasion to wage the ding-dong battle of myogenicism and neurogenicism, but to Lewis's positive assertion, that fibrillation of the auricle is the cause of cardiac irregularity, I would oppose the suggestion that irregularity of the ventricle is the cause of a stuffed auricle with attendant abortive and irregular contractility, which is graphically represented by tracings which Lewis designates fibrillation.

In the enfeeblement due to toxins generated by a severe tonsillitis the stability of the nervous system is frequently much impaired and its reflex irritability raised. I remember on one occasion, in dealing with such a case, inducing a profound syncope on piercing the tonsil with a bistoury. The syncope amounted to death for the time being. Every function of life was in abeyance, and the patient's pupils were wide and insensitive to light. The "death," I am convinced, would have persisted but for the artificial aid of manual respiration, which fortunately succeeded after a time in restoring "life." I am aware that in using these terms in such a case the patient's "death," like Mark Twain's once reported demise, may appear to some to have been "grossly exaggerated," but I am convinced that had the patient been left unassisted he would have remained "dead." He was resuscitated through a stimulation of his nervous system, for there was no direct cardiac massage.

I still maintain, therefore, that the disturbances of cardiac motion which we have been considering are originated in the nervous, not in the muscular system of the heart, and that they may be induced by any exertion, emotion, enfeeblement, or reflex irritation, which tends, under certain circumstances, by accelerating the action of the heart or otherwise, to cause the muscular factor in this or that part of the organ to escape from the control of the nervous system. The full flood of myogenicism at present flowing may be expected to subside.

The physical signs, however, upon which I desire to dwell more particularly on this occasion are the absence of bruit in the tachycardial heart; the triple rhythm audible at the apex, as in the case I have related; the so-called crescendo murmur so characteristic of this lesion in many cases; and the arrhythmia. What is the *meaning* of these signs?

In the case I have related there were four phases as regards the audible signs:

1. A period of accelerated regular action, in which the first and second sounds resembled one another in duration and character—a "tic-tac" rhythm, as it has been called, in which no adventitious bruit was audible.

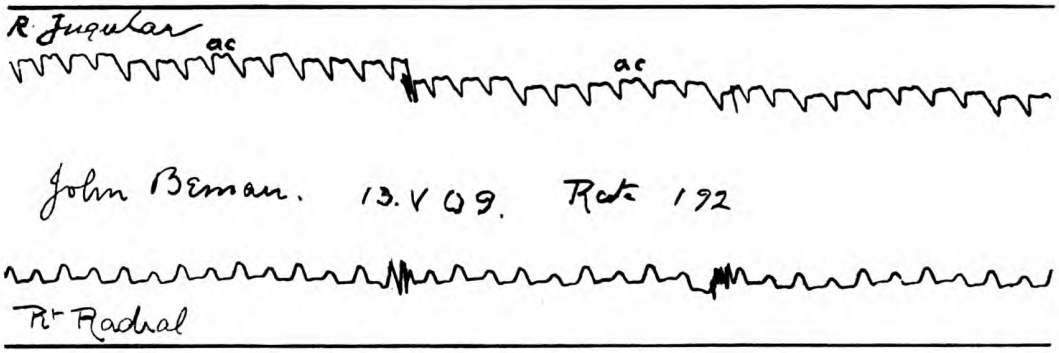
2. A period of slow action, in which there were triple rhythm at the apex and reduplication of the second sound at the base, when bruit was likewise absent, except in so far as it was represented by a bruit-like admixture or modification of the *last* of the sounds at the apex.

3. A period somewhat suddenly inaugurated by the complete presence of a characteristic and loud crescendo murmur at the apex, accentuated first sound, and disappearance of the triple rhythm, while the reduplication of the second sound persisted—the time interval or duration of this reduplication at the base being the same, so far as the ear could determine, as when the triple rhythm with slow rate was present.

4. A period just prior to the relapse of this case into the second regular tachycardia, when the heart was arrhythmical, moderately accelerated (114), and still presented the presystolic crescendo bruit, which was abolished by the succeeding regular tachycardia, the latter being suddenly followed by triple rhythm, slow rate, and a bruit noted as diastolic; this, again, yielding to the characteristic presystolic crescendo murmur with restored cardiac force, with which the patient left the hospital.

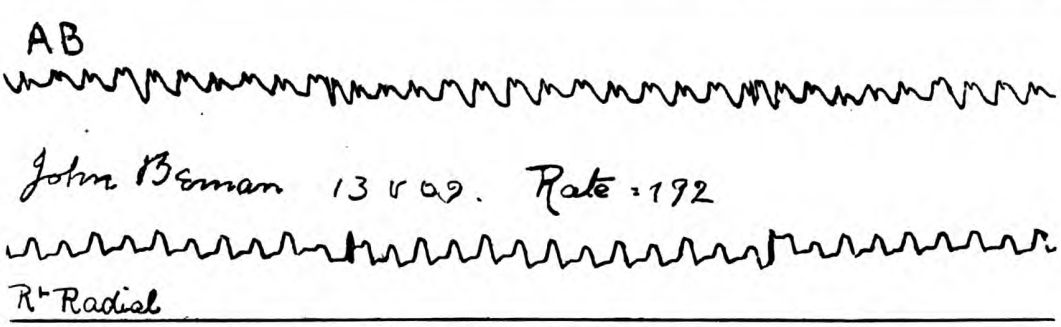
(*a*) Any acceleration of cardiac action tends to modify the auscultatory signs attending valvular disease when these are

FIG. 1.



Jugulo-carotid and radial tracings of the tachycardia.

FIG. 2.



Cardiogram and sphygmogram of the same.

well marked. If acceleration be accompanied by increased cardiac force or augmentation, in which case the quickening is usually moderate, bruits may become audible which are otherwise silent. When, however, acceleration is accompanied by depression, when the rate is usually greatly increased, bruits otherwise present may become greatly modified or altogether inaudible, and this whatever their anatomical situation. The abolition of the bruit in the first phase of the present case exemplifies this fact, the blood pressure merely registering 95 mm. of mercury and the rate being tachycardial. The cervical tracing shows almost a fusion of the jugular and carotid waves, if there be any jugular wave, while the radial pulse is greatly reduced in size (Fig. 1), and the cardiogram does not register a separate auricular systole (Fig. 2).

This jugular tracing shows what I understand is termed the "ventricular type" of jugulo-carotid pulsation. Personally, I venture to think it merely registers the carotid wave with the diastolic interval represented by a slightly notched and almost level top without any representation of the jugular wave or auricular systole whatever.

I presume a case such as this is one which is sometimes now described as one of auricular tachycardia, the substantive denoting the condition of the ventricle, and the adjective indicating the assumed cause of ventricular disturbance. But if this be so, I should take exception to the correctness of the expression.

By auricular tachycardia I understand an accelerated action affecting the auricle and not shared by the ventricle. This condition I have described elsewhere[3] under the term "jugular embryocardia," from the audibility as well as registrability of the auricular contractions, and Dr. A. F. Hertz and Dr. Gordon Goodhart have described a similar case.[4] What the auricle is doing in such ventricular tachycardia as was evinced by the case under discussion it is difficult to gather from the polygraphic record. According to Dr. T. Lewis, the string galvanometer shows it is showering erratic impulses upon the ventricle. However this may be, the chamber itself is not a very effective one. That the auricular reservoirs are full, probably too full, may be gathered from the increased percussion dulness, especially in the right heart, which such cases usually reveal.

It is curious how, under these circumstances, the subjective discomfort of the patient when at rest may be slight or altogether absent. There appears to be an almost continuous flow of blood in a thin stream through the chambers of the heart without the marked alternation of aspiration and propulsion, and, with the minimisation of these phases, the sonorous vibrations denoting particular murmurs disappear. This is true not only of mitral but also of aortic lesions.

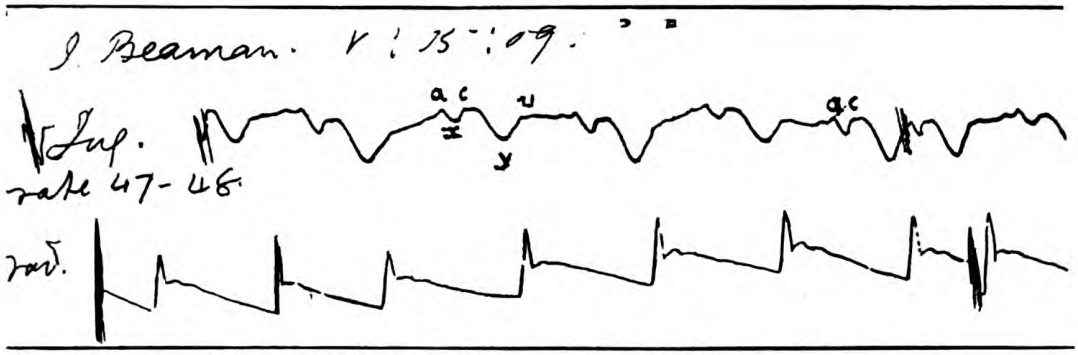
(*b*) In the second phase of the case the cardiac action though slow was still depressed, and the triple rhythm appeared at the apex. To what is this audible phenomenon due—what does it mean? The question has frequently been debated and is not yet decided.

There is no doubt concerning the first long sound of the apical triple rhythm. It is due to, and denotes, the systole of the ventricles. That one of the two remaining sounds represents the normal second sound of the heart is agreed, so far as I have been able to gather, by all who have considered the subject, but a difference of opinion exists as to which of these two sounds—the second or the third—is to be so regarded.

Dr. Sansom,[5] with whom Dr. Cheadle agreed,[6] regarded this triple rhythm (which the latter termed "reduplication of the second sound at the apex") as consisting of the usual first and second heart sounds, followed by a third due to the impact of blood in the diastolic ventricle upon the ventricular face of the mitral cusps. Dr. Cheadle also regarded this apical triple rhythm as indicating in childhood commencing mitral stenosis.[7]

Dr. Stacy Wilson[8] placed the so-called "third sound" after the normally occurring second sound, at the commencement of what he calls the period of ventricular relaxation, and ascribed it, so far as I can gather, not to the first inrush of diastolic blood into the ventricle, which he regards as synchronous with the second sound, but to a retarded inflow when the stage of *expansion* is over and that of relaxation begun.[9] But it has to be borne in mind that the apical triple rhythm may occur in the absence of mitral stenosis, and presumably, therefore, in the absence of that auricular retention of blood which plays a part in Dr. Stacy Wilson's theory.

FIG. 3.



Jugulo-carotid and radial tracings of the retarded heart with apical triple rhythm.

An examination of the tracings in the case related, at that phase of it which manifested the apical triple rhythm, shows retardation associated with low arterial pressure. The radial sphygmogram shows a small apical angle and an undue approximation of the predicrotic and dicrotic notches, which are not well marked. The cervical tracing shows a lengthening of the *ac* interval proportionate to the degree of retardation, and also the presence of one auricular contraction corresponding to the succeeding ventricular systole—that is, the auricle and ventricle are equally retarded. The cardiogram shows little beyond a lengthening of the diastolic interval, and the auricular contraction is only occasionally and very faintly indicated. (Figs. 3 and 4.)

If these radial and jugular tracings be compared with those taken when the triple rhythm was abolished, and the crescendo presystolic murmur established, it will be found that the rate has increased in the latter, that the apical angle of the radial sphygmogram is wider, the predicrotic and dicrotic waves more distant from one another and more distinct, and the measurement of the *ac* interval on the cervical tracing less, while the auricular wave is more distinct. A cardiogram taken at the same date shows increased cardiac vigour with well-marked events: first a rise which coincides in time with the dicrotic notch on the radial sphygmogram, and like it presumably denotes sigmoid closure; then the filling auricle, with, in most instances, a rounded rise presumably due to auricular systole; next the abrupt ventricular rise with a series of small vibrations over the proximal apex, which might be regarded as contemporaneous with the sharply accentuated first sound; and finally, the fall of the

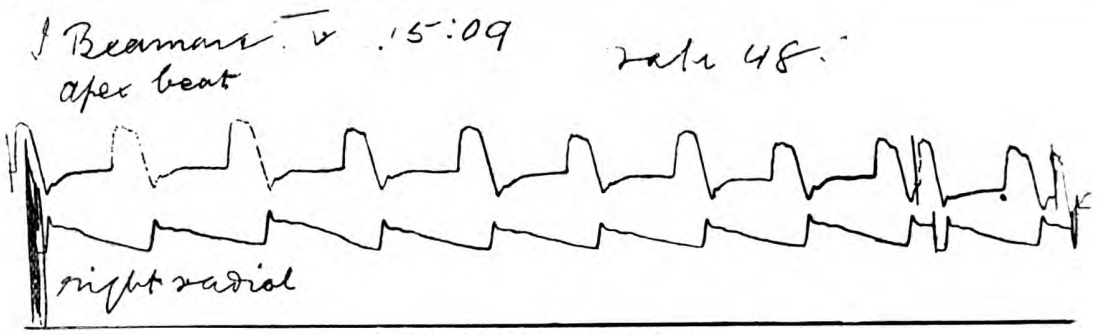
needle on retreat of the heart at the end of systole. The pulse-rate was assumed to be the same during both these tracings, and the increased spacing in Fig. 6 was probably due to a less rapid spin of the clockwork (Fig. 5).

A certain value no doubt is to be attached to these graphic distinctions, although from the dubious nature of some wavelets on such tracings, especially as affecting veins, I feel disposed to vary the old tag which refers to the unreliable character of the Danäi by saying: *Timeo undulas venosas et scientam docentes.* The fact remains, however, that the heart evincing the triple rhythm is, as compared with that in which this rhythm has ceased to be shown, a heart associated with a lower pressure in the circulation as a whole, and necessarily one in which the muscular action of all the chambers of the heart has less efficiency than in the organ from which that sign has disappeared.

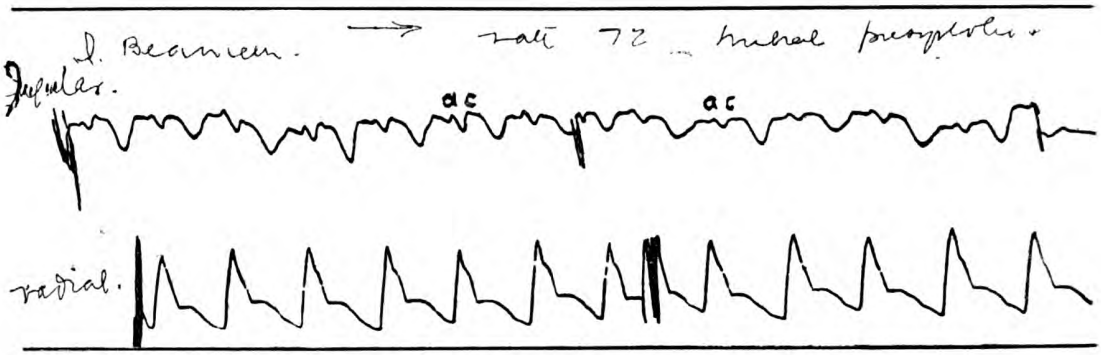
Now, the triple rhythm at the apex (and it is always at the apex and in a limited area there—namely, the inner apex or, more precisely, an area usually extending from the apex beat to the left edge of the sternum and upwards as far as the fourth rib) may frequently be temporarily abolished by quickening the heart's rate. Thus if a patient manifesting this sign when recumbent be asked to sit up in bed, during the acceleration caused by this movement the triple rhythm disappears, giving place to the usual first and second sounds, until the heart has again gained its average rate and tone for the time, when the sign may reappear. This change *may* be owing to mere acceleration, but I am inclined to think that, under these circumstances, there is also a temporary augmentation or increase in the force of the heart beat. Some imported incident in the cardiac cycle is eliminated by this accelerated action. What is this incident?

FIG. 4.



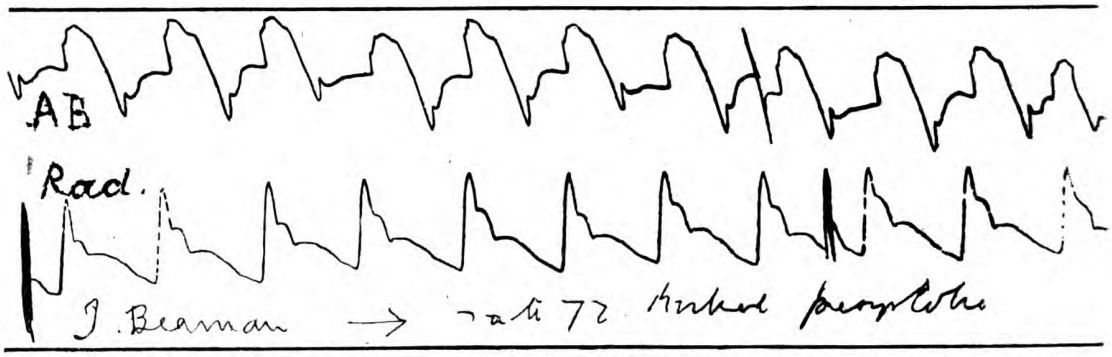
Cardiogram and sphygmogram of the same.

FIG. 5.



Jugulo-carotid and radial tracings from the restored heart with crescendo bruit.

FIG. 6.



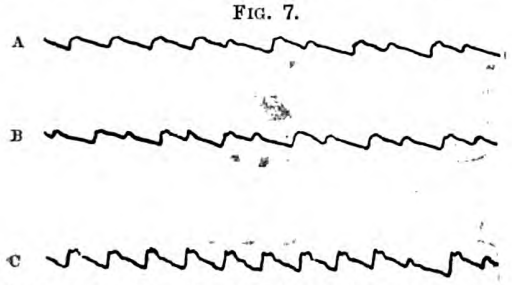
Cardiogram and sphygmogram from the same. (The upper tracing in this figure was originally marked "jugular" in the notes of the case. It is manifestly the cardiogram.)

Were we to accept Dr. Sansom's view of the cause of this sign, the incident eliminated would be the impact of the diastolic blood on the mitral cusps. But this, surely, should occur, whatever the position of the patient or rate of the heart. On the hypothesis advanced by Dr. Stacey Wilson the change of position and quickening of the heart should modify the condition of ventricular "relaxation," and with it the mitral valvular state which emits the third sound with the inflowing retained blood.

It is probable that the changed position of the patient, with consequent acceleration of the heart, has, as I have suggested, some such effect as causing the ventricle to act more vigorously for the moment and so to reduce the distinction between diastolic expansion and relaxation, but to complete diastole the latter phase must still occur. In the theories referred to, the "third sound" is thought to follow the true second sound of the heart, and is, therefore, diastolic, place it where you will in diastole. I hold that it occurs at the commencement of diastole and place it at the first rise marked in the diastolic phase of the cardiogram in Fig. 6, which is also, though less distinctly, marked in the cardiogram in Fig. 4, on account of the less energetic action of the heart. This view is one the possibility of the suggestion of which appears to have occurred to Dr. Stacey Wilson, but which he only mentions as an interpolation to dismiss. When I say it appears to have occurred to him it is not quite stated by him as I should put it. "The other alternative," he writes,[10] "would be to believe in a second ventricular systole in the middle of the long pause, or to believe in an early and wholly unprecedented form of auricular activity. There is no evidence at all in favour of either of these."

The "third sound," it is true, follows a second sound at the apex, which is assumed on these hypotheses to be the normal second sound of the heart. But is it the second sound? If it be not, the third sound, of course, does not occur in ventricular diastole, but is followed by that phase. The so-called "third sound" may, in other words, be the true but altered *second* sound. In that case, what is the second of the three sounds of the apical triple rhythm?

FIG. 7.



Sphygmograms of quadruple, triple, and mixed apical rhythm from a case of double mitral disease.

A good many years ago, when in charge of the out-patients at the Great Northern Central Hospital, I had a woman under my care suffering from double mitral disease, who seemed to me to afford the clue to answer this question. She presented, when recumbent, a quadruple cardiac rhythm with a bigeminal pulse. (Fig. 7 B.) That is to say, a long systolic or first sound, was followed by a short diastolic or second sound, and this, by a short systolic, abbreviated first sound or extra-systole, while the latter was succeeded by a long diastolic second sound. On assuming the erect position, with some acceleration of cardiac action, the usual triple rhythm, with abolition of the bigeminal pulse, took the place of the quadruple rhythm associated with the above bigeminal tracing, and the sphygmogram showed that the short diastole succeeding the first systole had been eliminated and the extra-systole so closely approximated to the first systole as not to find separate graphic record, but to be nevertheless clearly distinguishable on auscultation as the second of three sounds audible at the apex. The tracing was anacrotic, but the registration of the extra-systole was absent, unless the anacrotic rise be regarded as such. (Fig. 7 C.) In transition from the recumbent to the erect position, and *vice versâ*, there was a mixed rhythm until the average rate was attained, when the rhythm became quadruple or triple according as the patient lay or stood—i.e., according as the heart's action was retarded or accelerated to a certain degree. (Fig. 7 A.) It will be observed that in Fig. 7 C, taken when the patient was standing, and exhibiting chiefly a triple apical rhythm, the event in the quadruple rhythm which was eliminated is the first shortened diastole of Fig. 7 B.

In the case which forms the text of this paper and in the case of *triple apical* rhythm generally, I would suggest that the second of the three sounds is a left ventricular extra-systole so closely approximated to the preceding systole as to be *graphically* unregistrable but nevertheless audible. If, however, we start with a triple rhythm, a slight acceleration and augmentation of the heart's action cuts out, on this view, the unregistrable but nevertheless audible extra-systole and leaves the normal single systole and diastole.

The apical triple rhythm, cantering rhythm or *bruit de galop*, consists of a long sound, followed by a short sound, while the latter is succeeded by a sound longer than the second, and when, as in the text case, the rate of the heart is slow and its action depressed, this third sound is as long as, or even longer than, the first sound. With some increase in the rate and power of the heart, there is some shortening of the third sound, which remains, nevertheless, a long sound as compared with the second, and may be, as it was in the text case, contemporaneous with a soft bruit, or, as it were, blunted by it.

As it is not possible to regard the second sound of the triple rhythm as denoting a hemi-systole of the *right* ventricle (for that would be for the right ventricle to contract after the left) and auricular systole, even if so clearly audible as this sound is, could not be imagined *immediately* to follow ventricular systole, it does not appear to me possible to regard the second sound of the apical triple rhythm as being other than such a ventricular extra-systole as I have described and which arises independently of any auricular prompting.

The apical triple rhythm then, on this showing, consists of a ventricular systole, closely followed by a regularly recurring ventricular extra-systole, and the latter succeeded by the second sound of the heart modified in character by the condition of ventricular muscular action.

But Hope's explanation of the second sound—namely, that it is emitted by the sigmoid valves of the pulmonary artery and aorta as they close prior to ventricular diastole—is that usually advanced, and when this closure is not simultaneous the second sound is said to be reduplicated. It was reduplicated in the case we are considering. If this solution be accepted as correct, how comes it that the tone of the third sound of the triple rhythm differs so much from that of the sigmoid closure when auscultated at the cardiac base,—that only *one* of the sounds when reduplicated reaches the apex when triple rhythm is present, and that the time interval between the reduplicated closure of the sigmoid cusps as heard at the cardiac base, and that between the second and third sounds of the apical triple rhythm differs so much—is so much longer at the apex than at the base?

To take the last point in this interrogatory first, it may be dismissed by remarking that, as has been shown or argued, the second sound of the apical triple rhythm is a ventricular extra-systole, and not the second sound of the heart. The greater length of time-interval between it and the succeeding sound has therefore no relation to the character or time-interval of the reduplicated sigmoid valvular note. The other two points are more difficult to explain.

The *tone* of the second sound of the heart differs at the cardiac apex from that it has at the base. It has a more membranous, papery, or valvular *timbre* at the base, while at the apex there is a more sonorous, deep, or what has been termed by some a more "muscular" note. When reduplicated at the base no reduplication need be heard at the apex, but the second sound is nevertheless audible there. Again, the second sound when reduplicated at the base may be heard reduplicated at the apex, with a longer time-interval and a deeper note for both the sounds. Or, lastly, the reduplicated second may be heard at the apex of much the same note and time-interval as at the base. These variations in the transmission of the basic sound or sounds to the apex are probably dependent upon variations in the force and tension of ventricular action, or, to use the language of to-day, in the contractility and tonicity of the heart muscle.

In the text case of this paper, during the phase of slow pulsation, when the triple rhythm was audible, there was a

[10] Loc. cit., p. 14.

reduplication of the second sound at the base with a short time-interval, which may be phonated as "trip." This was quite inaudible at the apex, but the period of its occurrence was later than that of the second sound of the apical triple rhythm, so far as I could determine.

If this third sound was, as I have suggested, the "cardiac second" sound and that sound was reduplicated at the base, only one of the reduplications reached the apex to the left of the sternum, and that altered in tone. If this was so, it must have been the sound emitted by the closure of the *aortic* sigmoid segments, if the second sound is to be accounted for by the closure of the basic cusps. The pulmonary arterial portion of the reduplicated second would under these circumstances be eliminated by transmission towards the right ventricle by way of the conus arteriosus.

The bruit admixture, as I have termed it, of the third sound in the apical triple rhythm was probably due to the weak flow of blood from the auricular reservoir through the stenosed mitral orifice, at the commencement of ventricular diastole, which coincides with the closure of the sigmoid cusps, the sound being heard through the murmur, just as the pulmonary second at the base may at times be heard through a diastolic aortic bruit, the bruit in the same way outlasting the tone-sound.

(*c*) In the text case, when cardiac force had recovered and the patient had a blood pressure of 135 mm. of mercury, with a pulse-rate of 72, a well-marked and loud crescendo murmur declared itself.

On the time and cause of this crescendo murmur much has been written. The late Sir William Gairdner's study of, and conclusions upon the subject had great influence in generalising the belief that the murmur was presystolic in time and its cause the forcing of blood through a stenosed auriculo-ventricular orifice by systole of an auricle whether right or left.[11] While this view has met with almost general acceptance, there have been dissentient voices, among which may be mentioned those of Dr. Howship Dickinson and Dr. E. M. Brockbank. The latter is a persistent advocate of the early ventricular systolic, as distinguished from the diastolic and presystolic conceptions of its nature. He has comparatively recently reopened the subject[12] and maintained his thesis with much spirit and ingenuity.

The crescendo murmur in the present case, which may be regarded as one of a type frequently met with, may be phonated by the sound *dur-r-r-ūp*, the long *dur-r-r-* being followed by the abrupt and short *ūp*. That this *ūp* synchronises with ventricular systole one may easily convince oneself by observing that it is immediately followed by the reduplicated second sound. It is the characteristic accentuated first sound pathognomonic of mitral stenosis. It may be audible, as I have already stated, in the left para-vertebral groove, although unaccompanied by bruit in that situation. When it occurred in the text case, the triple rhythm had disappeared. It represented the first *lūp* of the triple rhythm, shortened and emphasised by the accelerated and more powerful action of the ventricle. It is the altered first sound of the heart, the cause of which is still the subject of a difference of opinion. It has the high note of valvular impact. That is to say, of valve struck by blood under ventricular propulsion. When we come to consider which valve, however, we open the flood-gates of contention.

Dr. Brockbank[13] apparently regards the sound as not due even to a valve struck by blood, but to the "sudden and forcible impact of the hardened, thickened jaws of the diseased mitral valve." Personally, I feel disposed to regard the accentuated note as due in great measure to the impact of blood, not only against the aortic cusp of the mitral valve, but also and simultaneously, if not chiefly, on the lines of the late Sir Richard Quain's theory of the causation of the first sound of the heart, against the closed aortic cusps, which are more resistant to ventricular systole when, as in mitral stenosis, the chamber is less rapidly and easily filled by the blood to be projected. There is apparently some prolongation of ventricular diastole and auricular systole, and a commensurate shortening of ventricular systole. In other words, the higher note of the first sound denotes an aortic pressure *relatively* higher than under normal circumstances, together with less intraventricular pressure to overcome it. It only then remains to inquire into the meaning of the crescendo bruit which precedes this abrupt, high-pitched, and apparently shortened first sound.

Sir William (at that time Dr.) Gairdner illustrated his interesting paper on cardiac murmurs[14] by a diagram in which he depicted the auricular and ventricular systole, the diastole of the ventricles, the sounds of the heart, and a long pause intervening between the ventricular diastole and the succeeding auricular systole. George Gibson gives a diagram[15] in which he throws Gairdner's ventricular diastole and long pause into one; and Halliburton, in Kirkes' Physiology, gives a similar diagram, in which he names the post-ventricular passive interval the diastole of auricle and ventricle, taking the diagram from "Sharpey and Gairdner." To these I venture to add another on the same lines, which indicates more precisely the fact that, while auricular and ventricular diastole are ultimately merged into one, auricular diastole lasts from auricular systole to auricular systole, and therefore, in addition to the period (Fig. 8) of ventricular diastole, exists during ventricular systole. The longest *passive* incident in the cardiac cycle is auricular diastole. In other words, the auricular reservoir of blood exists both before and after auricular systole. In the present day, when one talks of cardiac events in decimals, the production of such a diagram may appear to some antiquated.

FIG. 8.

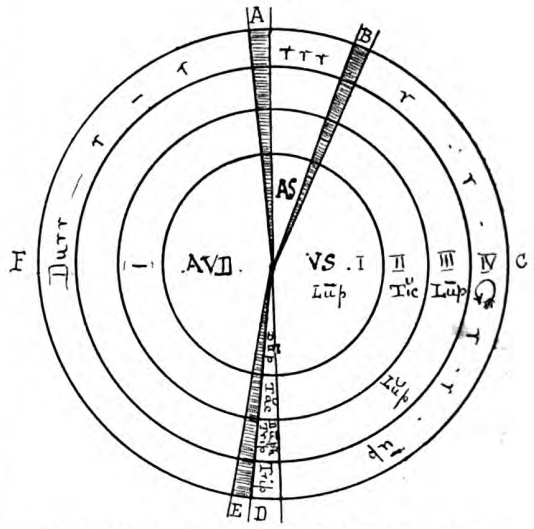


Diagram of the cardiac cycle to illustrate the conception of the phenomena given in the text. I. AS, auricular systole; VS, ventricular systole; AVD, auriculo-ventricular diastole. Lūp, Dūp, first and second sounds of the heart. II. Tic, Tāc, shortened first and second sounds of the heart; (—) greatly diminished diastolic pause. III. Lūp, Lūp, Dūph, ventricular systole, extra systole, and blunted second sound of the heart; Trip, reduplicated second sound. IV. A, termination of auriculo-ventricular diastole; A-B, auricular systole; B, commencement of auricular diastole; C, ventricular systole; D, reduplicated second sound at the base; E, commencement of auriculo-ventricular diastole; F, auriculo-ventricular diastole; Durr-r-r-ūp, crescendo bruit; curved arrow, a possible ventricular systolic and intra-ventricular contribution to the bruit.

The first active event in the cardiac cycle excluding venous pulsation, where myogenists say the stimulus to auricular contraction arises, is auricular systole. But the passive precedes the active, and both veins and auricles must hold blood before they can project it. The cessation of active systole, moreover, is followed by a period of active "expansion," to use the term employed by Dr. Stacey Wilson in the paper already referred to, before it reaches that of "relaxation" or pause. Diastole is thus in its commencement an active event whether we concede it dilatational muscle or mere elastic recoil. The physiological result is active aspiration. How powerful and important ventricular aspiration may be was never so fully impressed upon me as it was after my study of the case of sarcoma of the right auricle and ventricle, of which I gave an account to this society in 1908, and in which life was for long maintained chiefly through the

agency of the aspirative and propulsive power of the left ventricle.[16] We have then an all but constant reservoir of auricular blood and ventricular chambers of aspirative power proportionate to their musculature. Under these circumstances, once the blood current has been established, the escape of blood from the auricle has not to await auricular systole when ventricular diastole intervenes, but the latter itself commences a process of emptying the auricle which is terminated by auricular systole.

If one could conceive a heart brought into existence, in which no active event had ever taken place; in which, also, the passive auricle had a stenosed outlet and the chamber was filled with stagnant blood,—if *then* activity commenced with the auricle and was followed by the other events of the cardiac cycle, the first bruit resulting from the first auricular contraction would no doubt be a purely auricular systolic bruit. But the regular sequence of events once established, and the blood-supply constant, a mitral valve stenosed to a certain extent is, so far as I can see, bound to emit a ventricular suction murmur at some phase of ventricular diastole before the succeeding auricular systole empties that chamber. If, moreover, as seems probable, the short, abrupt first sound in mitral stenosis denotes a shortening of ventricular systole, then the long drawn out gurgle of the crescendo murmur in such cases can only indicate a relative lengthening of the other events in the cycle—namely, ventricular diastole and auricular systole.

In his interesting paper already referred to Dr. Brockbank adduces the microphonic sound-vibrations in the tracings given by Weiss and Joachim in support of his position. Joachim, however, states[17] that "in the cases in which the murmur was heard immediately after the second sound, the murmur-curve was continuous with the vibrations of the second sound; where a purely presystolic bruit was noted, vibrations first appeared in the latter part of the diastolic period." He further makes the interesting observations that the vibrations in the crescendo murmur *gradually* gained amplitude, and that no notable change could be detected at the point estimated to correspond with the occurrence of auricular systole.

These observations appear to me rather to support Dr. Frederick Taylor's interpretation of them[18] as indicating diastolic suction with auricular enforcement than Dr. Brockbank's views on the early systolic position of this sign. There is also much force in Dr. Taylor's remarks on the inaudibility of even loud presystolic bruits in the back. The vibrations are, in other words, in an *onward* current.

It is to my mind quite conceivable, however, that at the commencement of ventricular systole there may be an additional "churn" imparted to the presystolic gurgle by that action, but such addition must be fractional, intra-ventricular, and not due to actual hæmic reflux. It may, however, serve to suppress the audibility of the commencement of the first sound, which survives as the clear, sharp note already mentioned.

FIG. 9.

Jugulo-carotid and radial tracings of the arrhythmical phase.

FIG. 10.

Cardiogram and sphygmogram of the same.

(*d*) The fourth and last point which calls for comment in our study of the text case is the period of arrhythmia with moderate acceleration, which was succeeded by tachycardia and as suddenly replaced by bradycardia, triple rhythm, and diastolic bruit, to pass again into the phase of the presystolic crescendo murmur of restored cardiac force. All these points, except the arrhythmia with retained crescendo bruit, have already been discussed and need not again be considered in detail.

No subject has received more attention of late than cardiac arrhythmia. It may, of course, occur without any valvular lesion, but is much more frequently associated, when such a lesion does exist, with mitral than with any other lesions. When arrhythmia is found in association with aortic valvular disease, it is more frequently of the regularly recurring or rhythmical type. The arrhythmia of mitral disease, except when the result of the digitalis group (when bigeminal pulsation usually results), is generally an irregular arrhythmia,

[16] THE LANCET, Jan. 9th, 1909, p. 77.
[17] Archiv für Physiologie, Pflüger, vol. cxxiii., p. 372.
[18] Brit. Med. Jour., Nov. 13th, 1909, p. 1440.

and when the crescendo murmur continues to be heard under these circumstances it is most pronounced during the larger and fuller pulsations of the heart.

The arrhythmia of mitral disease may be transient or permanent, as also may be the arrhythmia of non-valvular disease. In the text case it was transient and ushered in a transient tachycardia. If we examine the tracings of this period we find that the chief feature in the arrhythmia is the shortening or elision of the ventricular diastolic pause. While this fact is apparent from the radial sphygmogram, it is most easily appreciated by a study of the cardiogram. A consequence of this condition, notwithstanding the incursion of extra-systoles of various sizes and an occasional systole of greater volume than normal, is to render irregular and imperfect the escape of blood from the auricular reservoir.

The jugular or cervical tracing necessarily participates in the irregularity of the sphygmogram and cardiogram, and the venous incidents in it are obscure and only occasionally to be observed with approximate reliability. There was no time record on the instrument with which the tracings were made in the text case, but measurement with compasses from points of simultaneous interruption in the various tracings suffices to indicate the situation of the chief arterial incidents. From these the site of venous events may be surmised. In these tracings they are chiefly conspicuous by their absence. While I claim no more than an average dexterity in the use of the polygraph, I do not think the absence of the venous incidents in these tracings is so much a measure of my own clumsiness as of the ineffective contraction of an irregularly overfilled auricle. This overfilling is, I suggest, determined by the irregular and imperfect action of the ventricles and chiefly by that elision or shortening of the ventricular diastolic pause to which I have already referred. When we come to the consideration of the probable cause of the latter condition we again reach debateable ground.

I confess that to my mind there is, by assuming certain data, more to be said for Mackenzie's "nodal rhythm" in this connexion (which is nothing more or less than an acknowledgment of the non-auricular activity of the ventricle with a myogenic explanation thrown in) than for Lewis's auricular fibrillation; for, in such arrhythmia as we are considering, I believe the ventricular irregularity is the chief cause of the auricular distension and disturbance and probably precedes it. Yet I prefer to both a neural hypothesis, which sees in the irregular action of the muscular factor its irregular modification by the contending forces of inhibition, augmentation, and acceleration which in action alter the smooth regularity of the detached or decerebrated rhythmical muscle cell. When arrhythmia becomes permanent the auricular reservoir becomes more tolerant of its surplus blood content by dilatation, and so the heart less prone to uncontrolled tachycardia. It is scarcely possible to conceive a persistent auricular fibrillation, although a persistent auricular tachycardia, unshared by the ventricle, is known to exist.

THE FUTURE OF THE CRYSTAL PALACE.—Lord Tenterden has issued a circular letter asking those interested in the future of the Crystal Palace to give their approval to certain schemes by which it may be converted into a permanent memorial to his late Majesty King Edward VII. The first scheme suggests the use of the Crystal Palace as a headquarters for the National Aero Corps, which is to be composed of individuals and societies owning and using flying machines of all kinds. The building would be used for all purposes connected with aviation and would include instruction in flying and the sale of machines. It is proposed that every Englishman being a member of the National Aero Corps shall have the privilege of being trained as an aeronaut or as an aviator, so as to enable Great Britain to maintain her prestige in the air as she has done on the sea. The second scheme is practically an amplification of the first, one of the chief features being the construction of a high-speed electric railway from West Central London direct to the Palace. Lord Tenterden invites signatures in support of his proposals in order that they may be sent to the Lord Mayor, with the hope that the King Edward Memorial (London) Committee will adopt one or other of the proposed schemes. In connexion with the National Aero Corps a First World's Aerial Exhibition will be held at the Crystal Palace from Dec. 1st of the present year to Jan. 31st of next year.

ACTIVE LOBAR COLLAPSE OF THE LUNG AFTER ABDOMINAL OPERATIONS.

A CONTRIBUTION TO THE STUDY OF POST-OPERATIVE LUNG COMPLICATIONS.

BY W. PASTEUR, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL, BERNERS STREET, LONDON, W.
CONSULTING PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY ROAD, E.

As the term used in the title of this communication might be misunderstood, it is necessary that I should briefly explain the meaning I attach to the words "active lobar (or massive) collapse of the lung."[1] It is a state of active deflation of the organ, affecting one or more of its lobes, which occurs under certain conditions, in the absence of any obstruction of the air-way, and is probably always due to disturbance of the muscular mechanism of respiration.

Imperfect power of expanding the thorax has, it is true, long been recognised as a cause of collapse of the lungs; but, judging by the references to this subject in the literature, the collapse implied is of the patchy or lobular variety (of passive origin, and not to be confused with the one here under consideration). It is sometimes accompanied by a state of general incomplete expansion of the organ which is often referred to as partial collapse; wrongly, I think, inasmuch as this condition of imperfect expansion does not present any of the well-known naked-eye characters of collapsed lung, to which the term collapse should, in my opinion, be restricted.

Active lobar collapse can be best studied after death from respiratory paralysis. Thus, in five cases of diphtheria in which the diaphragm had been completely paralysed for some days the lower lobes, especially the right, were found on post-mortem examination to be totally emptied of air, generally sinking entire in water and presenting in a typical form the naked-eye appearances of collapsed lung.[2] Since my attention was first drawn to this subject some 20 years ago by the cases just referred to, I have examined the lungs in some 15 instances of the condition arising in the course of a number of different diseases. In every one of them the lower lobe was the part primarily and most profoundly affected. The reason of this probably is that failure of the diaphragm is relatively common, whereas complete loss of power in the muscular groups which are the direct expanders of other parts of the lungs is a somewhat rare event and one which does not often lead to a fatal issue. There are cases on record in which active collapse of the upper lobes has been recognised during life, though, so far as I know, there is at present no record of a fatal case. Although the state of collapse brought about in this way does not apparently differ in any important particular from that caused by, say, a complete pneumothorax, a very large pleural effusion, or complete blocking of a main bronchus, the actual cause of the deflation is obviously different. The emptying of the lung in pleural effusions is probably due to pressure from without, while in the case of a plugged bronchus the collapse which takes place is generally held to be due to a passive removal of the air in the portion of lung beyond the bronchial occlusion. Neither of these processes will explain the extreme deflation of active collapse. The cause of this condition, however, is susceptible of an explanation which is at once rational and perfectly simple—an explanation, moreover, which completely meets the observed facts. Whenever—whether as the result of paralysis or of temporary reflex inhibition of muscular action—the distending force acting on the lungs becomes less than that of the elastic and muscular agencies which tend to cause its contraction, these latter, so to speak, take charge, with the result that the affected portion of the lung rapidly empties itself of its contained air. Whether the deflating force is elastic or muscular, or both, I do not pretend to say; but this is not a material point. The cases about to be described prove—as conclusively as clinical evidence can prove—that sudden deflation of large tracts of lung may occur after certain surgical operations with a fairly well-defined train of attendant symptoms and physical signs.

[1] For fuller information on this subject consult the Bradshaw Lecture of the Royal College of Physicians of London, 1908. Vide THE LANCET, Nov. 7th, 1908, p. 1351.
[2] Loc. cit.

CASE 1. *Radical cure of hernia; active collapse of the right lower lobe 24 hours after operation; recovery.*—The patient was a man aged 23 years. Radical cure of left inguinal hernia was performed on Nov. 8th, 1909. The case was perfectly aseptic throughout. Anæsthetic: gas, ether, and chloroform. Twenty-four hours after operation the patient was suddenly seized with pain across the lower part of the chest and alarming dyspnœa without warning of any kind. When I saw him, within three hours of the onset, he was in a state of extreme dyspnœa, the face being dusky and the alæ nasi moving strongly. On examination of the chest cardiac dulness was found to have been entirely obliterated. The heart was beating in the fourth interspace just outside the right sternal border. There were no adventitious sounds and the action was regular, 132 per minute. Traube's space was resonant and the stomach resonance was normal. The whole of the left front and the axilla was hyper-resonant (suggesting pneumothorax); the backs were not examined. There was loud exaggerated breathing all over this area, with well-marked vocal fremitus, but no râles. Right side: The percussion note was about normal below the clavicle, becoming gradually dull towards the base. Breathing was very weak all over the right front and the axilla, becoming quite inaudible over the dull base. Vocal fremitus was much diminished. The liver dulness was slightly higher than normal. The epigastrium was normal. The temperature rose rapidly to about 103° F. with the onset of the symptoms. Oxygen was administered frequently during the night. On the morning of the 10th the patient was much better. The cyanosis was much less and there was only slight dyspnœa. The temperature was 99° and the pulse was 84. Heart dulness was still absent on the left side. On the 12th the heart impulse was discernible just to left of the sternum and the patient was improving rapidly. After this date steady improvement was made. The heart did not fully regain its normal position until the 25th. Examination with the orthodiagraph on Dec. 1st revealed normal action of the diaphragm on both sides. There was some enlargement of the right heart, otherwise everything was normal.

CASE 2. *Abscess in the right side of the abdomen following operation for right inguinal hernia; incision and drainage; active collapse of the right lower lobe on the fourth day; recovery.*—The patient, a man aged 37 years, had undergone an operation for right inguinal hernia in a provincial hospital in September. The wound only ceased to discharge a fortnight before the patient left the hospital on Oct. 30th, 1909. A month later pain in the abdomen above the wound was felt. A lump formed in this situation, causing great pain and constipation. On admission a hard mass occupied the right side of the abdomen; it was superficial, rounded, and slightly moveable. This was incised on Jan. 15th. A considerable quantity of pus was evacuated, and there was much surrounding inflammatory swelling. Daily peroxide syringing was practised with kreolin fomentations. On the 19th the patient was taken suddenly ill at 2 P.M., with some pain and a feeling of tightness across the lower part of the chest. The house surgeon found some weak tubular breathing at the right base, with a few crepitations. I saw the patient at 4 P.M. The left chest looked full. There was a drum-like percussion note all over the left front and axilla as low as the sixth rib. The heart dulness was obliterated, the impulse being most distinctly felt in the right fifth space three-quarters of an inch from the right sternal border. Epigastric pulsation was well marked. The breath sounds were much exaggerated all over the left front and axilla, with prolonged expiration (not suggesting consolidation). Vocal fremitus and vocal resonance were both somewhat diminished. On the right side the breath sounds were normal over the upper lobe but very weak over the lower lobe, which was dull (relatively) on percussion. The breath sounds in this region were weak and bronchial, and ægophonic in one spot. Vocal resonance was much diminished. No râles were audible. There was not much dyspnœa. The sputum was white and frothy. On the following day there was bronchial breathing over the right base behind, with some crepitations and exaggerated breathing over the left lung. After this the symptoms rapidly subsided. The temperature rose to 101° F. at the onset, but fell to normal again on the following day. There was no dyspnœa worth mentioning after the first day. Weak breathing and impaired resonance at the right base persisted for 11 days.

CASE 3. *Left salpingectomy for pyosalpinx; active collapse of the left lower lobe on the third day; recovery.*—The patient, a strong, well-built married woman, aged 24 years, was admitted on April 4th, 1910, complaining of a painful tumour to the left of the uterus. On the following day a left pyosalpinx was removed, a drainage-tube being inserted alongside of the colon. The patient had much abdominal pain during the next two days; on the seventh it was chiefly felt in the neighbourhood of the ensiform cartilage. The temperature had risen slowly since the operation with large morning remissions; at 10 P.M. on the 7th it was 100·4° F., and at 10 o'clock next morning it had fallen to 98·8°. There had been slight cough for the last 36 hours. On the 8th the patient complained of pain beneath the lower end of the sternum and between the shoulders. On examining the backs the breathing was noticed to be weak over the left base. The respirations were 24. At 2 P.M. she was suddenly seized with alarming symptoms of dyspnœa and cyanosis. It was noted that the onset of the dyspnœa was not absolutely sudden, the cyanosis apparently preceding it. The temperature had risen to 103°, the pulse from 106 to 120, and the respirations to 40. The patient looked desperately ill. She was sweating freely and complained of chilliness, but there was no rigor. She began to expectorate small quantities of viscid yellow sputum. The apex beat could not be made out; the heart sounds appeared to be unaltered. Nothing abnormal was detected on pelvic examination. There was marked dulness over the left lower lobe and to a slight extent also at the right base quite low down. Breathing was practically inaudible all over the left lower lobe with the exception of the posterior apex. Vocal fremitus was diminished; vocal resonance was somewhat increased with a rather nasal quality of voice sounds. No crepitations were heard. At 10 P.M. the condition was unchanged. The temperature was 104·8°, the pulse was 132, and the respirations were 45. The heart's apex was felt beating in the left axilla (exact position not put down). The left base was as before, but very weak breathing with a few crepitations now audible. The right lung generally was hyper-resonant. (Massive collapse of the left base was diagnosed.) At 2 A.M. on the 9th (four hours later) the temperature was 101·8°, the pulse was 122, and the respirations were 40, all symptoms diminishing in severity. At 10 A.M. there was definite improvement. The apex beat was gradually moving back towards its normal position. The temperature was 99·8°, the pulse 120, and the respirations were 24. The dulness over the left base was diminishing both in extent and degree, expectoration (muco-purulent) was much freer, and there was no longer hyper-resonance over the right lung. The urine was normal. The bowels, which were confined for three days following operation, were well relieved by simple measures. Films and media (from the sputum) contained pneumococci, but not in sufficient numbers to suggest pneumonia. On the 10th the patient was better in every way, the lung dulness rapidly declining. The apex beat was in the nipple line. On the 13th the left base was normal, with the exception of a few moist sounds near the spine. The left chest, in the xiphi-sternal plane, measured 15½ inches, and the right 16½ inches. The patient went to a convalescent home on the 27th.

CASE 4. *Cholecystitis; cholecystectomy; massive collapse of the right middle and lower lobes early on the fourth day; recovery.*—The patient was a well-built fairly healthy married woman, aged 45 years. Cholecystectomy was performed on June 10th, 1910. (A "clean" case throughout.) Gas, ether, and chloroform were employed as the anæsthetic. The drainage-tube was removed on the 12th. On the 13th the temperature had risen to 100·4° F. There was mucus in the trachea which the patient was unable to cough up on account of pain in the wound. No abnormal signs were observed over the front of the chest, but the respirations had risen to 30, and there was slight distress in breathing. On the 14th at 7 A.M., after a fair night, the patient suddenly became rather blue, there was an appreciable increase in the dyspnœa, and the pulse had become rapid and thready (120), the respirations being 40. She rallied quickly after taking a little brandy. The chest was examined at 11.30 A.M. The apex beat could not be felt. The left chest in front was very resonant (hyper-resonant), the resonance extending a finger's breadth beyond the right sternal margin opposite the lower end of the sternum. There was loud exaggerated breathing all over the left side of the chest, with increased movement. On the right side in front the percussion note was resonant as far as the fourth rib; below this there was dulness increasing in degree towards the base. Behind at the apex resonance was fair, impaired in the interscapular region, and quite dull below the angle of the scapula. The breath sounds were weak over the posterior apex and almost inaudible over the remainder of the lower lobe, except on coughing, when faint tubular breathing could be heard. There were no moist sounds in the lungs. There was no heart dulness to the left of the sternum; the heart sounds were very faintly audible in this area, but distinctly audible on the right side of the chest, being most clearly heard in the right fourth space one inch inside the nipple. The patient had coughed up about two ounces of viscid greenish sputum in the last 24 hours. There was no pain in connexion with the onset of symptoms. The temperature, after touching 102·6° on the 14th, at 2 P.M. gradually fell to normal by the 17th. The pulse, which reached a rate of 140 on the night of the 13th, dropped below 130 on the evening of the 14th, and below 100 two days later. The respiration rate varied with the temperature. The case was remarkable in the prominence of the physical signs in comparison with the mildness of the symptoms. The dyspnœa was not continuous, as in other cases, but recurred at intervals throughout the 13th and 14th. It was at no time really urgent. The patient felt and looked better on the 15th, and was practically free from any unpleasant symptoms on the 16th. On this date the point of maximum intensity of the heart sounds had shifted to the mid-sternal line, but there was no appreciable change in the state of the right lung. The base was still dull and silent, vocal fremitus being absent. On the 17th the heart sounds were most clearly audible in the fifth left interspace, two inches from the mid-line, but were still distinctly audible to the right of the sternum, over the middle lobe. The signs of compensatory hypertrophy on the left side had disappeared. Two or three days later the patient had completely recovered.

CASE 5. *Gall-stone colic; cholecystotomy; active collapse of right lower lobe on the second day, with recurrent attacks of heart failure; recovery.*—The clinical picture of lobar collapse was somewhat modified in this case by the super-added symptoms of recurrent attacks of heart failure, but the physical signs observed were identical with those present in the other cases. The patient, a stout, flabby, full-blooded married woman, aged 49 years, was admitted for repeated attacks of gall-stone colic. She had suffered from breathlessness on any exertion for many years. On June 14th, 1910, an operation was performed, many stones being removed from the gall-bladder and several from the common bile-duct. At 10 P.M. there was much pain about the wound. One-third of a grain of morphia was administered hypodermically. The temperature was 98° F., the pulse was 84, and the respirations were 24. On the 15th the patient looked and felt comfortable throughout the day. The respirations, however, had risen to 40, but there was no inclination to cough. They fell again to 28 on the same evening. The temperature throughout the day was just below 99°, the pulse between 90 and 100. On the 16th, at 7 A.M., the patient suddenly became deeply cyanosed, with rapid shallow breathing (44) and very feeble frequent pulse (120). She appeared to be moribund. Brandy, strychnine, and oxygen were at once given, and within 30 minutes she had rallied in all directions. At 11.30 A.M. the wound was dressed. The opportunity was seized to make a rapid examination of the chest. Fronts: Compared with the left the right front looked flat, and the breath sounds were decidedly weak, while on the left the breath sounds were everywhere loud and exaggerated. Normal heart dulness absent. The heart was neither heard nor felt to the left of the sternum; the heart sounds were most distinct in the right fourth space two inches from the mid-line. The left front was everywhere hyper-resonant. Backs: The breathing was weak all over the right back, especially over the lower lobe where the percussion note was impaired, while there was loud exaggerated breathing all over the left back, with occasional rhonchi. Towards the end of the examination the patient had another bad attack of heart failure, which yielded in an hour to stimulating treatment. During the day she began to cough up a little viscid greenish sputum. The temperature varied between 100° and 101° throughout the day, falling to normal during the night. On the 17th the patient looked better; no further attacks of dyspnœa had intervened. The heart sounds could be heard to the left of the sternum as far out as the nipple line, but they were still loudest two inches to the right of the sternum. The apex beat could not be felt. The breathing was of equal strength on the two sides of the chest except at the right base, where it was very weak and bronchial; a few fine crepitations were audible on inspiration. Resonance was still impaired at the right base. The pulse was 100 and the respirations were 32; the expectoration was as before.

The patient had another sharp attack of heart failure in the evening, with deep cyanosis. On the 18th she complained of intense epigastric pain. The discharge from the tube to the common bile-duct was scanty, but purulent. The tube was removed and about two ounces of pus were expressed. The breath sounds in the right axilla, over the base, were still weak as compared with the other side. After this there was steady improvement and no further attacks of dyspnœa occurred. The temperature became normal on the 23rd. Cough and expectoration ceased on the 21st. On the 25rd the resonance was equal and normal all over both backs, the breath sounds were healthy, and all adventitious sounds had died away. The heart sounds were most distinctly heard on the left side, near the nipple line, but the apex beat was not yet palpable.

The special interest of Case 5 lies in the association of recurring attacks of heart failure with massive collapse. The symptoms in this case vividly recalled to my mind the "cardio-pulmonary crises" which were not uncommonly met with in cases of diaphragmatic paralysis after diphtheria.[3] The significance of the association is heightened by the knowledge that this patient was known to have a weak heart (? fatty), so that her condition approximated more nearly to that of the diphtheria cases than any of the other four.

I look upon these five cases as clear examples of active lobar collapse from reflex inhibition of the diaphragm, occurring most probably in otherwise fairly healthy lungs, and in the absence of inflammatory lesions of the diaphragmatic pleura or peritoneum, such as are almost invariably found in fatal instances of the condition after surgical operations on the abdomen. There can be little doubt, from a comparison of the two groups of cases, that it is the absence of associated lesions (nearly always septic) which accounts for the remarkable uniformity in the symptoms presented by post-operative cases with clean wounds[4]; and the fact that all the patients recovered shows that this complication, though very alarming in its symptoms, is not usually dangerous to life.

Now, as to the cause of active lobar collapse in these cases the following points are to be noted. 1. The cases of diphtheritic paralysis quoted above prove beyond question that arrest of diaphragmatic movement does cause massive lobar collapse of the lung. 2. My entire series of fatal cases (other than those due to paralysis) have, without exception, this feature in common—namely, the existence of a powerful source of irritation in the neighbourhood of the diaphragm within the area supplied by the vagus—that is to say, a condition of things in which reflex inhibition of that muscle might very readily be set up. 3. In four out of the five cases the lung affected is on the same side as the operation wound. 4. The disappearance of apex beat and heart sounds from the normal position and their displacement towards the affected side. 5. The sudden over-distension of the unaffected lung. 6. The almost complete silence over the affected lobe.

In the face of this evidence it is difficult to resist the conclusion that arrest of diaphragmatic movement is the cause of massive collapse in these cases; indeed, it seems almost impossible to account for the facts observed on any other hypothesis.

Why inhibition should occur and what is the precise nature of the irritation which determines the reflex I am not at present in a position to state. The course of the nervous paths is fairly obvious in the gall-bladder cases, and if, as there is reason to believe, the vagal ramifications in the abdomen extend to the whole length of the intestine, we may suppose that in all these cases the source of irritation lies within the vagus area of distribution. It may be anticipated that with fuller data to work upon light will be thrown on this as well as on other features of these cases which are still surrounded by much uncertainty.

Review of the Symptoms.

One cannot fail to be struck by the close resemblance of the initial symptoms to those of pulmonary apoplexy, nor is this surprising, seeing that in both conditions a large tract of lung tissue is suddenly thrown out of action. The onset of active collapse, however, is not invariably sudden (Case 4). There may be a prodromal period of some hours during which the patient looks and feels ill. The temperature is rising gradually and there may be slight distress of breathing with some duskiness of surface. I would suggest that this prodromal phase may coincide with a partial deflation of the lung, owing to gradual diminution of inspiratory power, and that the acute symptoms only arise when the danger-point has been reached and the now unopposed contracting force causes active collapse of the affected lobe. It would help, also, to explain why in such cases the symptoms are generally less urgent than when a sudden cutting-off of the expanding force is the first event in the series.

The usual symptoms of active lobar collapse are: sudden dyspnœa and cyanosis, generally accompanied by more or less pain in the lower part of the chest. Cough is often present, but not a marked feature, as a rule, in uncomplicated cases: there may be some greenish viscid expectoration, but rusty sputum has not been met with. There is immediate loss of mobility on the affected side of the chest. The movement on the healthy side, which often looks full in comparison, is exaggerated. The breath sounds are diminished on the affected side, becoming almost, or quite, inaudible over the base, which is always relatively dull on percussion, sometimes very dull. Weak tubular breathing can occasionally be made out over the affected base, a fact which readily accounts for the diagnosis of pneumonia which is usually made in these cases. There can be no doubt that many cases have passed muster as post-operative pneumonia which were really instances of active collapse.

The healthy side of the chest presents, often in a marked degree, the usual characters of compensatory hypertrophy, though it may be doubted whether an enlargement of the lung so rapidly accomplished can be purely physiological. The margin of the enlarged lung often reaches beyond the opposite border of the sternum. By far the most striking sign of the condition, however, is the shifting of the apex beat towards the affected side (Cases 1 and 2). Where the apex beat cannot be felt the position of the displaced heart must be determined by auscultation. In cases of right-sided collapse the normal heart dulness is obliterated. The appearance and percussion of the healthy side of the chest in these cases at first blush suggest pneumothorax.

Another feature of some diagnostic value is the short duration of acute symptoms and the rapid return of the heart towards its normal position. The affected lung also begins to show signs of returning function within a very few days.

The heart signs require somewhat fuller consideration. The displacement towards the affected side is very difficult to account for. According to current views as to the effect of unilateral loss of intrapleural tension, the heart and mediastinum in these cases should be drawn towards the healthy side. The opposite is what actually takes place, unless we are to suppose that the silent, inactive lobe is healthy and the large over-acting lung the seat of disturbance, which is absurd. It may be pointed out, however, that the pathological conditions in the cases under consideration probably differ from those under which the phenomena of disturbances of intrapleural tension have for the most part been studied, in that the evidence tends to show that the disturbance here is mainly due to removal of the muscular expanding force, in the absence of pleural or pulmonary lesions, or of any effusion into the pleural sac. I do not, however, wish to imply that these paradoxical signs are mainly to be accounted for by loss of intrapleural tension; other factors are at work: (1) the effect of sudden collapse of a lobe on the right ventricle (acute dilatation); (2) masking of the heart dulness and apex beat (in right-sided collapse) by the over-distended left lung; (3) the effect of the rapid distension of the healthy lung in preventing displacement of the mediastinum towards the unaffected side. It is probable that all these factors are contributory. The initial symptoms suggest right heart failure, and the orthodiagram taken on the twenty-second day in Case 1 revealed definite dilatation of the right ventricle, which could not otherwise be accounted for. But they do not account for the displacement of the heart towards the left axilla in Case 3, in which there was collapse of the left lower lobe. The explanation of this must, I think, be left open for the present.

The description of the symptoms given above does not apply equally to active collapse occurring in septic cases. Here the clinical picture is much more involved and the diagnosis often difficult on account of the presence of other morbid conditions.

[3] See Cases Illustrating the Association of Respiratory Paralysis with Cardio-pulmonary Symptoms in Diphtheritic Multiple Paralysis, Transactions of Clinical Society of London, vol. xxviii., p. 111.

[4] Although pus was discharged from one of the drainage-tubes in Case 5 for two or three days there were no signs of general pus infection.

I shall have attained the object I had in view if the publication of these cases serves to direct the attention of surgeons to the symptoms and apparent frequency of reflex inhibition of the diaphragm after abdominal operations. It is doubtful whether the occurrence of this accident is even generally known; indeed, the whole subject of post-operative lung complications is in need of closer investigation than it has yet received. Purely medical in their nature and manifestations, they do not appeal to the surgeon. If physicians were more frequently afforded the opportunity of studying the initial stages of the medical complications of the post-operative state I believe that much additional light could be thrown on the nature, and, consequently, on the treatment of these conditions.

I feel sure that when the true history of post-operative lung complications comes to be written, active collapse of the lung, from deficiency of inspiratory power, will be found to occupy an important position among determining causes. In a future communication I hope to deal with the group of cases in which massive collapse was found at the necropsy.

Chandos-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TWO CASES OF POLIOMYELITIS IN ONE HOUSE.

BY C. R. SUTHERLAND, L.R.C.P. & S. EDIN.,
AND
WILLIAM ROBINSON, M.D. DURH., F.R.C.S. ENG.

As cases of poliomyelitis are being reported as occurring in epidemic form in different parts of the country, we have thought it right to send the following notes referring to two young brothers who were attacked with the disease within four days of each other. The family consists of father, mother, and three sons; the father is a gardener and the family live in an isolated house about two miles from Leamside in the county of Durham.

CASE 1.—Wm. H——, aged 12 years, bathed in the river Wear for the first time in his life on August 9th last. A week later symptoms of a feverish cold developed, and on the 19th he was first seen by one of us (C. R. S.). He then complained of feeling "ill all over," with headache and pain at the back of the neck. His temperature was 99·4° F., he was very restless, and there was slight delirium at night. There was no vomiting, rash, or sore throat. Two days later the headache and pain in the neck had increased, and there was now pain in the legs and in the lumbar spine. He could not turn over in bed and his lower limbs were found to be paralysed, and his right arm could not be raised higher than a right angle from his body. The reflexes were lost. Sensation was unaffected, but there was marked tenderness in the affected muscles. The bladder and rectum were normal. The temperature became normal in a few days, and when seen by us both together on Sept. 18th we found marked wasting of the right arm and both lower limbs, the knees being kept semi-flexed. He could not draw the legs up nor stretch them out. The patellar reflexes were gone; there was no ankle-jerk; the cremasteric and plantar reflexes were normal. He could flex but could not extend his toes. Sensation was normal; but pain was elicited when the legs were gently pulled straight and on grasping the calf and thigh muscles. The bladder and rectum acted normally. There was no response to faradism in the muscles attacked. He turned himself over from his back on to his face by the aid of his arms with great difficulty. His right arm was very helpless, his grasp being very feeble.

CASE 2.—Philip H——, aged 7 years, brother of the former patient, bathed in the river Wear on August 13th and came home "shivering with cold." A week later he became ill with exactly similar symptoms to those of his brother; but he was more restless and sleepless, and the pains in the legs and thighs were very severe and caused him to cry out when moved or lifted even so late as Sept. 18th, when we both saw him together, and there was considerable wasting of the thighs and legs, especially of the extensors. The muscles were very tender when pinched or stretched. There was also loss of contractibility to the faradic current. The bladder, rectum, and cutaneous sensibilities were unaffected. The skin was peeling, especially on the palms, though there had never been any sore throat or rash. He was now sleeping better.

The appetites of both the patients were good and their brain functions were quite normal. A younger brother had bathed with Philip, but beyond a slight febrile attack he has remained well.

Even in the epidemics of poliomyelitis it is stated to be very rare for two members of a family to be affected.[1]

The treatment consisted of rest, warmth, and sedatives; after the subsidence of the acute symptoms of gentle massage and passive movements; galvanism and the insistence of attempts of voluntary movements were also advised.

SUTURE OF THE FAUCIAL PILLARS FOR HÆMORRHAGE FOLLOWING TONSILLECTOMY.

BY ALFRED TENNYSON SMITH, M.D., C.M. ABERD.,
AND
HAROLD S. BARWELL, M.B. LOND., F.R.C.S. ENG.

AN annotation under this heading appears in THE LANCET of Sept. 3rd (p. 745), in which it is stated that Dr. H. H. Gilpatrick[2] had found the method most efficient in three cases of severe hæmorrhage which had come under his observation. This has reminded us of a similarly successful case, a short account of which may serve the useful purpose of drawing attention to this valuable method of treating a very dangerous complication.

A boy, aged 10 years, was admitted to the Cray Valley Hospital suffering from enlarged tonsils and adenoids, and the operation was performed by one of us (A. T. S.) on Sept. 30th, 1908. Although somewhat anæmic and flat-chested, the patient was in fair general health and no history of hæmophilia was given. There was no excessive hæmorrhage at the time, but a large amount of blood was vomited two or three hours later and on several subsequent occasions. An ice-pack round the neck and ice to suck reduced the bleeding, which was found to come chiefly from the right tonsil. Calcium chloride was given in doses of 10 grains every four hours, but slight oozing continued until Oct. 5th, when another severe attack of hæmorrhage ensued. The ice-pack was repeated, the right tonsil was mopped over with adrenalin, digital pressure was applied, and the bleeding diminished. During the next ten days there were several severe hæmorrhages in spite of the internal administration of adrenalin in doses of 20 minims three or four times a day, and the boy appeared to be very ill, with sunken eyes and blanched mucous membranes. The pulse was 126 and the temperature oscillated between 97·2° and 100·2° F. On the evening of Oct. 15th he was seen by one of us (H. S. B.). The fauces were clean and there were no tags, but there was a little oozing from the bed of the right tonsil, which was covered with a thin layer of recent clot. A very little anæsthetic was administered and, with the patient in the right lateral position, the piliars of the right fauces were stitched tightly together with a continuous silk suture. There was no further hæmorrhage, the suture cut through the posterior pillar about the fourth day, and the subsequent history is uneventful. The pulse and temperature did not become normal until Nov. 14th and convalescence was very prolonged. After the first operation careful inquiry elicited the fact that the boy belonged to a family of "bleeders" and that he had had severe hæmorrhage after circumcision in infancy.

The suture must be passed from behind forwards, and the principal difficulty is caused by the extremely small space between the posterior pillar and the pharyngeal wall; a small needle with a very sharp curve is therefore essential. The pillars must also be sewn together through their entire length, and it is wise to begin at the lower end while thoroughly depressing the tongue, for this is the part which is most likely to escape attention.

Reviews and Notices of Books.

Diseases of the Colon and Their Surgical Treatment. Founded on the Jacksonian Essay for 1909. By J. P. LOCKHART MUMMERY, F.R.C.S. Eng., B.A., M.D., B.C. Cantab., Jacksonian Prizeman and late Hunterian Professor, Royal College of Surgeons of England; Senior Assistant Surgeon, St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, &c. Illustrated by coloured and other plates and numerous figures in the text, many of which are reproduced from the author's sketches. Bristol: John Wright and Son, Limited. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1910. Pp. 322. Price 10*s.* net.

THE colon has been much neglected. Dysentery has long been known to be due to ulceration of the colon, and malignant disease has been recognised as occurring in it, but apart from these, very little attention has been paid to diseases of the large intestine. Though constipation is chiefly connected with the colon comparatively little is known about its causes. Within recent years, however, the study of this section of the bowel has become much more extended, and improved methods of diagnosis have afforded a greatly increased amount of information on its diseases. Therefore the time has surely come when it is justifiable, and, indeed, almost imperative, that a special work should be devoted to the consideration of the affections of the colon.

Modern investigations have shown that food reaches the large intestine in a much shorter period of time than used to be imagined, and the use of bismuth in the food and the employment of X rays have given us much useful information as to the progress of the fæcal material along the large intestine. Mr. Mummery quotes some of the evidence that shows that anti-peristaltic movements normally occur in the large intestine. Other points in the physiology of the colon are described, and then the pathology of this portion of the bowel is discussed. The bacteriology is of great importance. Many have claimed that bacteria in the alimentary tract are essential to the well-being of the host, but the author does not agree with this, quoting the fact that in many animals in the Arctic regions the digestive tract is entirely sterile. In this climate, however, bacteria in this situation are unavoidable. The main bacteria present are described, and the author considers that the bacillus coli is not wholly harmful, for it is said to limit the number of other micro-organisms, but we are inclined to think that Mr. Mummery rates too highly the services of the bacillus coli. It may indeed be true that it has some influence in inhibiting the action of other micro-organisms, but it is of such pathological importance that we cannot appreciate greatly any slight beneficial action which it may have.

The diagnosis of diseases of the colon is given fairly fully, the use of the sigmoidoscope and of X rays being described. We agree with the author that diagnoses based on the passage of a rectal tube are quite valueless, and an illustration is given showing how a long rectal tube may curl up in the rectum. An interesting chapter is that dealing with congenital dilatation and hypertrophy of the colon. As to the operative treatment of this condition, when non-operative treatment has failed the author advises resection of the dilated portion. In one case Mr. Mummery performed appendicostomy and the patient did well. This is a much less serious operation than resection, and it should be given a trial. Volvulus of the sigmoid is a serious condition, and for chronic volvulus the author advises shortening of the meso-colon. The importance of adhesions of the large intestine in causing chronic invalidism and troublesome constipation is now being recognised, and here it receives careful consideration. One outcome of the employment of X rays in the examination of the colon has been the recognition of the fact that in many cases the mesocolon sags greatly as it passes from side to side, causing very troublesome constipation. The question of the etiology of intussusception has been much discussed, and Mr. Mummery's explanation is that it is due to a mass of indigestible food coming in contact with the ileo-cæcal valve. For the diagnosis between mucous and ulcerative colitis Mr. Mummery relies chiefly on the sigmoidoscope, and for both these forms of colitis appendicostomy is advised. In the chapter on malignant disease of the colon it is recommended that if the bowel above the growth cannot be entirely emptied before operation an artificial anus should be established before removing the growth. The remainder of the book, with which we have been favourably impressed throughout, is chiefly concerned with a description of the various operations performed on the colon.

A System of Syphilis. In Six Volumes. Edited by D'ARCY POWER, M.B. Oxon., F.R.C.S. Eng., and J. KEOGH MURPHY, M.C. Cantab., F.R.C.S. Eng. Vol. IV.: Syphilis of the Nervous System. By F. W. MOTT, M.D. Lond., F.R.S., F.R.C.P. Lond. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 502. Price £2 2*s.* net per volume; to subscribers, £10 10*s.* per set of six volumes.

IN deciding to entrust the writing of the whole of this volume of the "System of Syphilis" to one author the editors of the work undoubtedly came to a wise decision. The success of the scheme was ensured when Dr. Mott was asked to undertake the work. It would be difficult to find anyone better fitted for the task, qualified as he is to speak alike as a leading authority on the pathology of the nervous system, a distinguished general physician, and head of the pathological department of Claybury Asylum. The result has fully justified the judgment of the editors; the volume is one of the highest excellence. The claim made for it in the preface that it is the first comprehensive and authoritative statement of the recent advances in our knowledge of syphilis of the nervous system in the light of biological and biochemical research is indeed well founded.

The two most interesting chapters in the book are the second, dealing with the general pathology of syphilis of the nervous system, and the sixth, on the cerebro-spinal fluid in its relation to syphilitic disease of the nervous system. In the former Dr. Mott points out the striking resemblances that exist between the histological lesions of the nervous tissues of chronic trypanosome infections—e.g., dourine and sleeping sickness—and those of syphilitic and parasyphilitic lesions. As he shows clearly, trypanosomiasis corresponds with syphilis in being a disease characterised by successive eruptions due to the escape of trypanosomes from the blood stream into the lymph spaces of the tissues, where they set up a similar tissue reaction. In severe trypanosomiasis, as in severe syphilis, there is always a polyadenitis. It is possible that the chronic trypanosome infections more closely resemble the diseases which are termed parasyphilitic; but Dr. Mott in a considerable experience—he has examined the nervous system in over 30 cases of sleeping sickness—has found that the disease does not show the wasting and destruction of the neural elements to anything like the extent that we find in cases of general paralysis. Microscopically there are many features of striking resemblance in the histological changes seen in the sections of brains affected with acute general paralysis, syphilis, and sleeping sickness. The destruction and decay of cells and fibres is, however, much more striking in cases of general paralysis than in sleeping sickness, and this accords with the clinical symptoms, since in the latter disease the signs point to neural exhaustion rather than to destruction. Dr. Mott maintains that the primary decay of the neuron is the essential feature of general paralysis, the disease consisting

essentially in a loss of durability of specific energy of the cortical cells latest developed, and for this reason he does not agree with the view that general paralysis is a manifestation of quaternary syphilis.

The examination of the cerebro-spinal fluid in syphilitic disease of the nervous system is of such importance that it is not surprising Dr. Mott has devoted a special chapter to this subject. Lymphocytosis of the cerebro-spinal fluid when combined with other facts is an invaluable sign of syphilitic and parasyphilitic affections. Chemical examination of the fluid demonstrates that in general paralysis and tabes there is an increase in the amount of proteid present, and that the syphilo-positive hæmolytic reaction increases gradually with the progress of the disease. The antibodies, therefore, in the cerebro-spinal fluid accumulate in proportion as the decay of the neurons proceeds. In 46 cases of general paralysis under Dr. Mott's care examined for the Wassermann reaction 41, or 89·1 per cent., gave a positive result. After a critical examination of the results obtained by this method and of their interpretation, the author concludes that in the hands of competent observers it is a most valuable means of determining the existence or not of general paralysis. The substances found in the cerebro-spinal fluid of tabetics and general paralytics, which cause a precipitation or a deviation of the complement, are present in an amount proportionate to the activity and length of duration of the disease, and are lipoids or globulins arising from tissue destruction caused in some way by the action of the syphilitic virus. It is probable that in certain cases of syphilitic infection—e.g., general paralysis and tabes—the central nervous system, which in ordinary circumstances is protected against the loss of its lipoid substances, takes part in the process, and this is manifested by the presence of lipoids and globulins in the cerebro-spinal fluids, and these act as the antibodies in the reaction. This complex lipoid, as well as a specific globulin, increases in amount as the process of neuronic decay proceeds.

The general view, then, that Dr. Mott takes with regard to parasyphilitic diseases of the nervous system is that they depend upon two factors, the vital resistance of the patient and the specificity of the virus. All those conditions which, inherited or acquired, tend to active metabolism of groups of neurons functionally correlated, in conjunction with the syphilitic poison, will cause the nerve cells to exercise an abnormal metabolic activity in the production of antibodies against the toxic effects of the virus. For the further elaboration of this argument and a consideration of the possibility of the existence of a special neuro-toxic virus we must refer our readers to the book itself.

In considering the difficult problem of the causation of congenital syphilis in view of the discovery of the spirochæta pallida Dr. Mott draws attention to the researches of Leishman on the spirochæta of tic fever, and suggests that there may be an intracellular phase of the spiral organism, and if so that it exists in the form of chromidian particles which possibly play the part of the nucleus in a more highly developed unicellular organism. If this view be accepted, then we may suppose that the head of the spermatozoon is infected with such a granule, which subsequently multiplies and produces the syphilitic lesions; otherwise the explanation of infection may be that spirochætæ contained in the sperm may remain alive in the uterus and gain access to the developing embryo without infecting the maternal organism. Besides the many pathological and etiological problems propounded, to some of which in the light of recent researches Dr. Mott is able to supply the solution, the clinical side of the work is no less important and equally well written. Many of the clinical histories are particularly complete and interesting because the author is able to describe cases of syphilitic disease of the nervous system of which he has seen the early stages at a general hospital and the later phases in the Claybury Asylum.

The book is the best and most important work on syphilis of the nervous system which has appeared recently, it will certainly remain a classic for many years, and we offer our congratulations to Dr. Mott as its author and to the editors on this latest addition to their comprehensive and valuable "System of Syphilis." The volume is well printed and the illustrations are very good.

Diagnostic et Traitement des Maladies du Nez. By Dr. J. GAREL, Lyons. Third edition. With 145 figures in the text and 4 plates. Paris: Vigot Frères. 1910. Pp. 458. Price 7 francs.

ONE of the attractions in the perusal of a systematic work by a continental authority, particularly one so well known as Dr. Garel, lies in the expectation of finding points of difference between his ideas and those generally held in this country. The volume before us, which is an excellent practical handbook of rhinology for the use of students and practitioners, appeals to rhinologists as well, for the reason just stated. In its pleasantly written pages will be found, as promised in the preface, a reflection of the author's own practice, although not to the exclusion of other matters of interest; and particular pains have been taken to present his personal views with clearness and precision.

The first chapter is occupied with anatomy and physiology and is well illustrated with stereoscopic plates. In the second the methods and instruments for rhinoscopy are described. Under the heading of general semeiology in the third chapter, besides a description of the various symptoms produced by nasal disorders, an account is given of the modes of estimating the degree of permeability of each nostril, with pictures of rhinometers and a rhino-manometer. Some space is also devoted to the means of testing the sense of smell; and the olfactometers of Reuter and Onodi are figured and described. The fourth chapter deals with general therapeutics, including a short but valuable section on hygiene in nasal diseases.

The second part of the work is taken up with a description of each disease in turn. Atrophic rhinitis and ozæna, the one a definite disorder and the other a symptom common to several diseases, are discussed together, although, as the author observes, they are not synonymous; and it is curious to observe the confusion introduced into the subject by this arrangement. The vexed question of the etiology of atrophic rhinitis receives full attention; every fact of importance is noted, while no space is wasted in recording conjectures. Under the head of treatment, paraffin injections, so valuable in the hands of Moure, Brindel, and Broeckaert, are approved by the author, who finds, however, that this treatment fails in a certain proportion of cases. For removing nasal polypi, the author often prefers a galvano-caustic loop to a simple snare; and in the treatment of adenoids he makes use of an electric adenotome of his own device except in cases of young children.

The treatment of deviations and spurs of the nasal septum extends over more than 20 pages, owing to the inclusion of a number of methods which must now be nearly obsolete. Besides submucous resection, which suffices for nearly every case, we find here Asche's, Gleason's, and Moure's operations: the treatment of spurs by electrolysis, by electric trephines or drills, by saws, and by a variety of septotomes. The chapter on diseases of the accessory sinuses is good, but rather too short. For the confirmatory diagnosis of suppuration in the maxillary antrum, catheterism of the ostium is advised rather than puncture of the nasal wall; but for treatment by irrigation alveolar puncture is

till preferred. However, where a radical operation is required, some of us will cordially agree with Dr. Garel that Luc's operation is the best, and that an integral part of that procedure is the careful curetting of the antral cavity.

The book closes with a short chapter on the treatment of fractures and deformities of the nose. There is no index.

Diseases of the Heart and Aorta. By A. D. HIRSCHFELDER, M.D., Associate in Medicine, Johns Hopkins University. With an Introductory Note by L. F. BARKER, M.D., Professor of Medicine, Johns Hopkins University. London and Philadelphia: J. B. Lippincott Company. Pp. 632. Price 25*s*.

Dr. Hirschfelder's object in writing this book has been to present side by side the phenomena observed in examining patients and the facts learned in the laboratory, in order to show how each supplements the other and how each may be of advantage in diagnosis and treatment. It is probable that many of the results obtained in the laboratory have not yet attained practical importance because they have been scattered through medical literature and have not reached the eye of the clinician. It is, however, in the collaboration between the physician and the worker in the laboratory that real progress will be made. In accordance with this idea Dr. Hirschfelder has arranged his material so that the clinical presentation in each chapter is preceded by an introductory section dealing with the experimental pathology and the more fundamental principles of the subject, and these considerations have been used as a basis for frequent reference in the clinical discussions. We certainly agree with Dr. Hirschfelder when he remarks that the trend of clinical observation during the past two decades has been towards more accurate study of disturbances of function and towards the introduction of mechanical methods for their observation—methods of precision which are intended to supplement or supplant the older and simpler methods of physical diagnosis. Chief among these may be mentioned the study of blood pressure, the graphic studies upon alterations in cardiac rhythm by means of the venous pulse, and the outlining of the heart and vessels by means of the X rays. A good account is given of the various instruments and methods employed. Many of the results obtained are of purely scientific interest, whilst others are of considerable practical value.

Some interesting remarks are made on the subject of cardiac overstrain. The failure of the heart is traced through its varying stages from the simple fatigue of the normal heart in exercise, through the stage of primary overstrain to that of broken compensation, especial attention being devoted to the states of broken pulmonary compensation arising from failure of the left ventricle and of broken systemic compensation from failure of the right. The line of reasoning adopted in the consideration of broken compensation is well worthy of study, for the subject is presented in a manner not usually adopted by writers on cardiac disease. The chapters upon the individual organic lesions include discussions of pathological anatomy, pathogenesis, pathological physiology, symptomatology, and etiology, as well as notes of typical cases, their diagnosis, prognosis, and treatment.

Considerable space is given to the difficult question of purely functional disturbances of cardiac action. Paroxysmal tachycardia is discussed at length, and the views of several observers are carefully criticised. The treatment of this affection is still unsatisfactory, and the significant words of Dr. James Mackenzie are quoted: "In my early days, I, too, thought I knew how to stop attacks, but more extended experience has shown me that when they stopped it was from some cause which was unknown to me and which was independent of any means I employed." The important subject of pregnancy and labour in cases of heart disease receives adequate attention. The general practitioner is frequently consulted by both patients and their relatives on this point, and much useful information will be derived from Dr. Hirschfelder's remarks. We have read this volume with much interest and can recommend it to our readers.

LIBRARY TABLE.

A Beautiful Arm: A History of the Vaccination Delusion. By AMOS BOOTH (of Leicester). With an Appreciation of Mr. Booth's work by F. G. STEVENS (of Leicester). London: Sampson Low, Marston, and Co. Pp. 132. Price 2*s*. net.—The full title is an example of the inflated style of writing which characterises the whole book. The revision of the matter for publication has not been very careful, for we are told in the preface that "Those evidences are revealed by the photograph given as a frontispiece and will probably be as repellent to the ordinary observer as they are obvious." The frontispiece, unfortunately, is a portrait of the author. The opening chapter, headed "Crazes, Delusions, and Superstitions," teems with symptoms of a well-known disease, "cacoëthes scribendi." The whole book consists of the usual antivaccination diatribes, and contains no reasoned attack on the practice of vaccination. Mr. Booth begins the chapter entitled "Statistics" by an attack on the validity of statistics, especially statistics of vaccination and its results. He says: "It is undeniable that the most potent weapon the supporters of Jenner have used in trying to prop up vaccination and instil its 'blessings' in the minds of the people all over the world has been one-sided statistics." In spite of his depreciation of statistics, especially one-sided ones, Mr. Booth proceeds, on p. 90, to support his case by statistics as to the death-rate in Leicester, which he gives for the years 1868–72 ("with vaccination at its climax") as about 27 per 1000, being 5 above the general rate per 1000 for England and Wales. In 1888–9 with practically no vaccination the death-rate in Leicester was 17·5, and in all England and Wales was 17·9; while "at the date of writing, August 9th, 1908, the general death-rate per 1000 of the population of Leicester is 9·7, though the town is unvaccinated and un-smallpoxed." It is to be observed that Mr. Booth seems carefully to eschew the years 1892–3, when the town *was* visited by small-pox. Let us study as a contrast to Mr. Booth's statistics the following: "As the comparative immunity from small-pox of 'unvaccinated' Leicester has become a stock argument among antivaccinationists, it is especially instructive to see how the town fares when the disease happens to obtain a footing in it. The Leicester epidemic of 1892-3 was investigated on behalf of the Royal Commission on Vaccination by Dr. Sidney Coupland, and his report gives the following facts. Of children under 10 years of age there were: Vaccinated cases, 2; deaths, 0 = 0·0 per cent. Unvaccinated cases, 107; deaths, 15 = 14·0 per cent. Of persons over 10 years of age there were: Vaccinated (including doubtful cases), 197; deaths, 2 = 1·0 per cent. Unvaccinated cases, 51; deaths, 4 = 7·8 per cent. These figures are convincing enough by themselves, but they gain additional significance when the cases are arranged according to the severity of the small-pox. Dr. Coupland's report shows that of the 199 vaccinated cases, 17, or 8·5 per cent., were confluent; 20, or 10·1 per cent., were coherent; 50, or 25·1 per cent., were discrete; 112, or 56·3 per cent., were mild. Of the 158 unvaccinated cases, 79, or 50·0 per cent., were confluent (including malignant); 36, or 22·0 per cent., were coherent; 28, or 17·7 per cent., were discrete; 15, or 9·5 per cent., were mild." The above is taken verbatim from the article on Vaccinia as a

Branch of Preventive Medicine by Mr. Ernest Hart, in "Allbutt's System of Medicine" (1901). Our readers know what small-pox means; and they will appreciate, though they probably know the details already, the full inwardness of these careful and accurate compilations. We cannot expect such statistics to appeal to any reasoning power possessed by Mr. Booth or his adherents. Our profession does not claim that vaccination is an ideal process, but it is the best at our command for the prevention of wide epidemics of small-pox. We know what such epidemics mean.

JOURNALS AND MAGAZINES.

The Child, a Monthly Journal devoted to Child Welfare. Edited by T. N. KELYNACK, M.D. Vict. Vol. I., No. 1. October, 1910. London: John Bale, Sons, and Danielsson. Subscription, £1 1*s.* per annum. Single copies, 2*s.* each.—The object of this journal is to provide an authoritative and representative presentment of all subjects relating to child life. It seeks to serve as a sort of clearing house for the ready transfer and exchange of trustworthy information concerning truths relating to childhood. It is essentially medico-sociological and cosmopolitan, opening its pages to writers of all nationalities, parents, educationists, philanthropic workers, physicians, and politicians. This first number contains articles by eminent British and foreign medical men, headmasters of schools, and principals of children's homes and orphanages.

The Dublin Journal of Medical Science.—To the September number of this magazine Dr. G. Arbour Stephens contributes an interesting paper on the Therapeutic Qualities of Calcium Permanganate, which he finds very useful in cases of gastric affection (ulcer, inflammation), as well as in lead poisoning and in malaria. Theses by Dr. Marius Anné Diemont on Mouth-breathing, and by Dr. William Leggett on the Present Position of Tuberculin Therapy appear in the same issue, the latter not being concluded in this number.

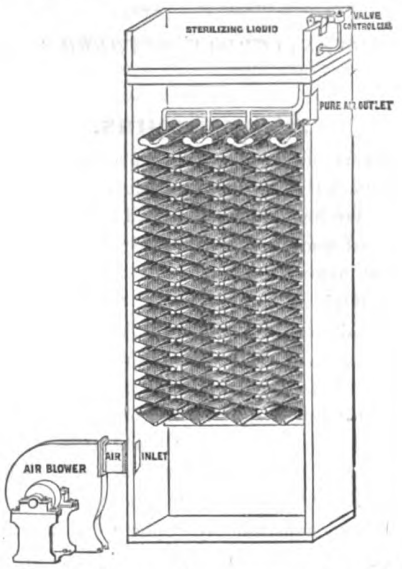
The Bristol Medico-Chirurgical Journal.—In the September number Dr. W. Kenneth Wills records a curious case in which an anomalous cutaneous eruption was apparently due to the action of the B. diphtheriæ and cleared up under the use of antitoxin. Dr. J. M. Rattray writes on post-graduate study, and Dr. J. Michell Clarke on the treatment of leucocythæmia by X rays, which he finds capable of producing some improvement but not cure of the disease. Dr. William Cotton applies some mathematical principles to the estimation of the size of internal organs, of which shadows are thrown on the fluorescent screen.

The Medical Chronicle.—The only original matter in the September issue of this journal is a report on vaccine therapeutics. The authors, Dr. G. E. Loveday and Dr. Albert Ramsbottom, conclude that the method is useful in genito-urinary tuberculosis, staphylococcic infections, streptococcic cellulitis, and gonococcal arthritis. They also believe that in acute pneumonia inoculations are of value and that estimations of the opsonic index may be useful aids to diagnosis. A memorial notice of Mr. John Edward Platt records the career of a careful surgeon and conscientious teacher, whose early death is much to be deplored.

New Inventions.

THE ROBERTSON, RINTOUL, AND SPENCER APPARATUS FOR THE PURIFICATION AND STERILISATION OF THE AIR.

THE accompanying illustration will convey a general idea of the principle upon which this air purifier acts. In so many words, it is an efficient scrubber which, however, removes not only macroscopic but microscopic impurities also. Careful bacteriological experiments have shown that the apparatus is capable of removing from the air passing through it practically all the organisms present. Petri dishes containing gelatin have been exposed to the ingoing air and to the effluent, with the result that while liquefying, pigment-forming organisms were abundantly developed on the former plate the latter gave practically negative results. It is interesting to learn that the apparatus was originally designed for recovering the acetone vapour from air in operations in which that volatile substance is



used as a solvent. The results were so good and led to such an important economy as to suggest that the apparatus might be of service for other purposes in which pure air is a desideratum. So far perhaps the most important commercial application has been the purification of the air of breweries. As is well known, the uncertainty of the character and quality of beer arises chiefly out of the attack upon malt liquor by foreign organisms. Beer is readily liable, in fact, to disease, but if the brewing operations are conducted in an environment of pure air the product is invariably pure and healthy and uniform in character and quality. The wort can be aerated successfully when the air employed is purified by this apparatus. There are obviously indications of the apparatus being employed with success in higher applications, as, for example, in the purification of the air in public buildings, in the hospital ward, the operating theatre, and so forth. The good results obtained by this system are, no doubt, a sequel to the attention which has been paid to detail, having regard also to economy of working.

The system consists in blowing air through a slowly descending stream of viscous liquid (sugar, dextrin, glycerine) containing an inoffensive germicide, dripping down over loosely-woven strands of cord arranged in zig-zag fashion. This arrangement exposes to the air the largest possible purifying surface without obstructing its velocity. The illustration shows the situation of the strands of fibre in the box, there being only just sufficient space between the strands to permit of the passage of the air, which is so broken up that it is forced to come into intimate contact with the viscous fluid and be sterilised by it. The air is thus not heated and not thereby devitalised; its fresh quality is not taken out of it. The essential point in the system is the very intimate contact that is effected between the air and the germicidal viscous fluid. There is apparently no limit as to the capacity of a machine for purifying the air on this plan, and the attention of medical officers, sanitary authorities, and others may well be drawn to the advantages which the application of this system to the purification of air offers. The makers are Messrs. W. J. Fraser and Co., Limited, of 98, Commercial-road, East London.

LONDON HOSPITAL MEDICAL COLLEGE: SCHORSTEIN LECTURE.—This lecture was delivered on Oct. 3rd, in the anatomical theatre, by Dr. Robert Hutchison, physician to the hospital, who took as his subject Congenital Pyloric Stenosis.

THE LANCET.

LONDON: SATURDAY, OCTOBER 8, 1910.

Æquanimitas.

ALL engineers and mechanicians are aware of the fact that when an engine has been running perfectly steadily for some time defects develop, and if unchecked lead to disaster; and one of the most common is that a wheel gets slightly "out of true," so that instead of the axis of revolution occupying the centre of a circle it occupies one of the foci of an ellipse. In the political world as well as in the physical world, the same phenomena are visible from time to time, and at the present moment the general political engine in this country seems to be running irregularly for the keynote of mundane matters is unrest. In the labour world unrest is paramount in the engineering trade and the cotton trade, as in railway and shipping organization; in politics, and not in this country alone, the atmosphere is by no means clear; and, to come to close quarters, in our own profession there are doubt and distrust as to the future with reference to many questions. Poor-law reform and the reconstruction of the public health service exercise the minds of many; the problem of quackery appears to grow more difficult of solution; the practical difficulties of medical education are increasing. In all these matters it may be said that the axis of revolution has shifted so that the running of the machine is impaired, and just as the inanimate engine requires a level-headed engineer to deal with its defects and to remove them, so the animate engine requires its governing faculties to be brought into play, and the chiefest of these is that cast of mind which used to be considered particularly British—namely, the faculty for seeing both sides of a question and of taking misfortune with calmness.

It may be argued that medicine has but little to do with politics and that political and labour unrest do not affect the profession of medicine. But though this is true from one point of view, and though, thank Heaven, the verities of science remain verities in the hands of their exponents despite the political bias, the creed, or the colour of their exponents, yet from another point of view medicine may be said to be all politics, regarding the word in its literal sense as expressing the relations of men one to another as they live in society. What are these relations but the main province of modern medicine? Questions of public health, of the prevention of disease, of housing, feeding, clothing, and sanitation in general, of whether the rising generation shall be given due opportunity to become a healthy race, all these questions in the main turn on politics, and all are certainly medical in the surest sense. The prosperity of the community is obviously the broad objective of the politician, and health—national health and individual health—becomes every day more and more a question of wealth. Can a nation and the items which compose it live adequately free from care and with reasonable leisure and opportunity for recreation, with healthy dwellings and sound food, is a question which centres round one thing—Can the nation afford to pay the bill? We do not go so far as to answer the question for this country, for much the same reason that Dr. JOHNSON gave to the inquisitive lady—"ignorance, madam, sheer ignorance"—but we are certain that no one ever entered into financial contracts with better success because he was in a condition of muddle and unrest. Equanimity is what we all want. Unrest is not in itself a matter to be deplored for the body politic, which, like the human body, may be said to be a collection of units, some superior, some inferior, but all dependent the one on the other. In the human body the rise in temperature which follows on a bacterial invasion is really an index of chemico-physiological changes which the invaded body is making to protect itself and to maintain its efficiency as a living whole. Similar febrile perturbations arise in bodies politic and bodies social when the necessity for readjustment of old-standing conditions is pressed upon the more conservative elements of the social organism. The intensity of the fever may indicate either a very sharp attack or a very ready response by the powers resisting the invasion. That large and wide-reaching changes in the whole social construction of the country are not only being demanded but are going to arrive within the near future there can be no doubt, and the problem to be solved is how these changes can best be brought about with the least disturbance of political physiology. Unrest there must be, but what we want is equanimity to face the necessity—equanimity lest unrest should degenerate into muddle.

It is on such considerations as the foregoing that we venture to urge the cultivation of the *æqua mens* in its widest sense, of the mind that is not unduly exalted, of the mind that is able to see that there may be something worthy of consideration in the arguments of an opponent. In the treatment of the human body an overdose of remedy may result in the death of the body cells as well as of the invading bacilli or of the adventitious tissue. Calmness and the avoidance of meddlesome surgery are precautions which hold as strongly for the treatment of the diseases of the body politic as for those of the human body. The stress and hurry of modern life form an environment which militates against the judicial and impartial consideration of problems at all times difficult of solution, and doubly so in these days. But we have only recently seen how in the presence of a great national grief the old British faculty of self-restraint could assert itself, and how political passion could be stilled. We may plead, then, that in the near future, on the assembling of the great Council of the Nation, both the public in general and those whom they send to represent them will cultivate the "equal mind," and remember that great problems which nearly touch the well-being of the nation may be argued with calmness and with consideration for the opinions of the opposite side. Only so can we hope to see decisions which, even if not a complete solution of the difficulties, may at least satisfy the greater requirements of the problems.

The Medical Addresses.

THE Introductory Addresses of the Medical Session now opening have been founded upon topics which, on the whole, appear to cover a somewhat larger area of thought than has been usual with them; and perhaps that which departed most completely from the commonplace ideal was the elaborate comparison instituted by Mr. E. W. ROUGHTON, at the London School of Medicine for Women, between the several characteristics and capacities of the sexes. We are not quite sure that his conclusions would in all cases be accepted without hesitation by those to whom they were addressed; but they had at least the merit of being free from ambiguity. He asserted, in quite plain terms, that the differences between the sexes are deeper and more far-reaching than costume or political disability; and at this last he glanced so slightly, and so completely without any expression of a wish for its removal, as to suggest either that the highly cultivated women to whom he spoke are not to be numbered amongst the ranks of the female suffragists, or else that he was himself quite superior to any attempt to gratify his audience by a concession to opinions which he presumably does not entertain. He even went so far as to introduce into his discourse a quotation from Dr. HARRY CAMPBELL, setting forth that the powers of self-reliance, origination, and invention in woman have at best been only feebly developed, and that the sweetness of character of which so many suffragists are openly scornful is, and is likely to remain, her most distinguishing characteristic. Closely allied to this is "her capacity for dissembling," a capacity for which the only suggested use is on the occasions, sometimes arising in the practice of medicine, when it is necessary "to deceive a patient in her own interest." Mr. ROUGHTON advised his lady students, "as a rule," but apparently as a rule to which there may be exceptions, to "say what they mean and mean what they say"; and he then proceeded to discuss differences between the rate of physiological development in the sexes, as well as differences in its nature which are answerable for organic and permanent differences of temperament and character. At the present time, he said, most women employ male doctors because, having little or no confidence in themselves, they find it difficult to place any in their medical sisters; but he gave no support to the profane legend that the patients, when suffering, find that they receive more sympathy from the male sex than from their own. This is, we hope and believe, an invention of the misogynist; and Mr. ROUGHTON must evidently be of the same opinion, for he speaks of gynæcology as the department of professional work in which it is important that women should excel. On the whole, it may be doubted whether his views would be endorsed by the distinguished pioneers of female medical education, but it is nevertheless plainly desirable that the attention of lady students should be called, at least on suitable occasions, to the difficulties as well as to the prospects of the career on which they have chosen to embark.

At University College Hospital the Dean of SALISBURY delivered an address which was chiefly in praise of poetry, and which incidentally introduced a quotation in which Lord MORLEY gave expression to that ignorant impatience of the claims of physical science which in this country is the distinguishing qualification of the professional politician, and one of the chief causes of the disasters which his ascendancy entails upon the community. KING EDWARD VII. asked a famous question about disease—"If preventable, why is it not prevented?" and the answer is, of course, that ignorance of science which is so great a source of national weakness, and which some critics would say that our system of government might have been designed in order to perpetuate. The Dean of SALISBURY is of opinion that "the special subjects on which medical men must occupy the main power of their minds are impediments in the way of complete self-development"; and he fears that concentration of the mental energies in one direction must leave the other powers and capabilities of the mind unused and cause them to dwindle and die. With great respect for the Dean, whose long ministration at St. Peter's, Vere-street, made him to a particular degree for many years the pastor of the London consultant, this appears to us to be very nearly nonsense, and we should meet his appeal to PASCAL, which he employed as a text, by a counter appeal to a much greater man, JOHN HUNTER, who wrote to JENNER "Don't think, but try." The so-called thinking which is unchecked by experiment is in its very nature futile, and has landed a succession of speculative philosophers in as many labyrinths of conflicting and only half-intelligible hypotheses. The man of science, in the true sense of the word, is called upon, not only to exercise his imagination upon the loftiest of all problems, the problems connected with the structure and government of the universe, but he is also called upon to control its exercise by the constant discipline of an appeal to fact. There can be no narrowness in work that ranges from the nebulæ of our system to the revelations of the ultra-microscope; while the average politician's evaluation of science is presumably about as trustworthy as that evaluation of the French language by Mr. LILLIVICK which may be found in the history of "Nicholas Nickleby." When the Dean of SALISBURY approaches the subject of poetry he is, we think, on surer ground; but we doubt whether the daily perusal which he advocates is of equal efficiency with that systematic storage during youth of which HALLAM has spoken in such noble words. He describes how, in MILTON'S blindness, the remembrance of early reading came over his dark and lonely path like the moon emerging from clouds. "They who, though not enduring the calamity of MILTON, have known what it is, when afar from books, in solitude, or in travelling, or in the intervals of worldly care, to feed on poetical recollections, to murmur over the beautiful lines whose cadence has long delighted their ear, to recall the sentiments and images which retain by association the charm that early years once gave them, they will feel the inestimable value of committing to the memory, in the prime of its power, what it will easily receive and indelibly retain. I know not, indeed, whether an education that deals much with poetry, such as is still usual in England, has any more solid argument among many in its favour than that it lays the foundation of intellectual pleasures at the other extreme of life."

At St. Mary's Hospital Sir ARTHUR CONAN DOYLE brought all the charm of his literary style to bear upon his illustrations of the hundred ways in which variations of health control or modify the actions of mankind, often, indeed, of the individuals whose influence over their fellows is the most far-reaching and the most important; and he showed how completely medicine and the phenomena with which medicine chiefly deals are interwoven with all the currents of life, from those which go to the making of history to those which affect only the humblest individuals. He showed how it becomes the practitioner to avail himself, not only of all the resources of his art, as these are commonly understood, but of all the conditions of human feeling by which the patient may be rendered more responsive to his touch. "A strong and kindly personality," an "exuberance of vitality and kindliness" are indeed, as he declared, potent auxiliaries to the healer; and, as these conditions are practically incompatible with ill health, he might with entire correctness have urged upon his hearers the duty of living wisely themselves in order to be the better able to inculcate the practice of wisdom upon others. The enemies against which the physician is called upon to contend have recently, indeed, been to a great extent dragged from their hiding places into the open, and can now be assailed with weapons of precision; but the complete efficacy even of these must always be largely dependent upon the generalship with which they are massed and directed upon their objective. At Manchester, Professor WILLIAM THORBURN laid stress upon the view which is sometimes neglected, but is none the less just, to the effect that even some of the most brilliant successes of the operator may be regarded as being in one sense of the nature of defeats, and that we should look forward to an ultimate replacement of the art of surgery by the still more perfect methods which it is our duty to seek, and to which it may be our privilege hereafter to attain. At St. George's Hospital a discourse upon the merits and faults of the current system of prize-giving as a stimulus to education and as a measure of its effects concluded with an earnest appeal to the givers of endowments to remember not only the pupil, but also, and even preferably, the teacher by whom his work is guided, and who, by the very nature of his pursuits, is at present heavily weighted in those competitions of life in which his knowledge qualifies him to excel. If education is to command the services of the best possible teachers it becomes more important to provide professorships than scholarships.

Hereditary Aspects of Nervous and Mental Disease.

AS a part of prophylactic therapeutics the subject of hereditary disease assumes a constantly increasing importance. Problems of vast consequence to the individual and to society can in all probability only satisfactorily be approached when our knowledge of heredity becomes fuller than it is at present, while the advice which is occasionally asked as to marriage and the procreation of children can only be more than faint-heartedly given while our opinions remain based upon nothing more substantial than surmise. Many are aware that there is a powerful biological school which is sceptical of any transmission of acquired qualities. By an obvious association of ideas it seems absurd, if this hypothesis be correct, to forbid marriage to those who have in their own persons evidences of diseased qualities which they have acquired. But even WEISMANN himself admits that germ-plasm may be modified by changes in nutrition occurring in the rest of the organism, and with this large exception conceded the path of the physician becomes better marked. For the moment the question of the transmission of acquired characters is perhaps of academic interest only, for it is apparently on all sides admitted that the germ-plasm may be injured by disease and by implication may be incapable of perfectly performing its functions: an imperfection which can undoubtedly eventuate in death and which may be presumed sometimes to result in something short of death, and to which we give the name disease.

In this limited sense, at any rate, disease is hereditary. Controversy, however, arises if we pass beyond these bounds. In the case of epilepsy there is no shadow of doubt that members of successive generations of certain families exhibit various epileptic phenomena; so much we may affirm. But to pass from this statement of indubitable fact to its explanation is at present out of our power. It is possible that in epilepsy there is transmitted a nervous system which is particularly liable to phenomena which in our crude way we liken to explosions or storms; or it may be that the nervous system is one peculiarly susceptible to certain toxins; or lastly, to bring the etiology within WEISMANN'S admission, it is possible that a toxin has interfered with the growth of the germ-plasm, and that, as a consequence, in the next generation the germ-plasm has been defective and the body-plasm has reciprocally been affected. Such hypotheses seem almost endlessly possible. The mystery only deepens when we come to the consideration of those diseases in which a generation is missed and a female transmits to a male. Here the hypothesis of toxic affection would appear to be of minimal validity. Dr. F. W. MOTT, in the Huxley lecture delivered this week at the opening of the medical session at Charing Cross Hospital, has once again drawn attention to the occurrence of certain nervous diseases in successive generations of certain families, the diseases for the most part being of a character in which toxic etiological factors could hardly be suspected; for instance, myotonia congenita, the myopathies, Huntington's chorea, and hereditary ataxia. It is remarkable, however, how singularly defective our statistics on these matters are, and that such as we have are of little or no value from a scientific point of view. With this there is, nevertheless, a preponderance of feeling among experts in favour of the importance of heredity in the production of feebleminded-ness, insanity, and certain organic and functional nervous disorders. From figures which Dr. MOTT adduces the interesting fact emerges that in insanity there is a greater incidence of "transmission" from parents to offspring through the female side than through the male. It would appear, too, that there is a tendency for insanity not to proceed beyond three generations, and that as a rule the family then undergoes a happy extinction. Such matters as these and many others Dr. MOTT has illuminated in his

admirable address which is published at p. 1057 of our present issue. There can be but little doubt that with greater artificiality in the preservation of the species, undoubtedly concomitant with advancing civilisation, there must arise inquiry into the less instinctive and more artificial methods for its healthy continuance. Herein lies the demand for eugenic knowledge, while from such work as that of Dr. MOTT we learn the immense way we have to go before we can even hope to see daylight.

Annotations.

"Ne quid nimis."

THE KING AND THE TOURING CLUB OF FRANCE.

IN response to a suggestion made by Sir Francis Bertie, the British Ambassador in Paris, His Majesty King George V. has graciously accepted an honorary membership of the Touring Club of France. At almost the same time His Majesty King Albert I. of Belgium accepted the same membership. Those who are acquainted with the excellent work accomplished by the Touring Club of France will rejoice at the well-merited compliments thus conferred on it. It is not as tourists but as sanitary reformers that we welcome the action of their Majesties, for that is the side of the club's work in which we are interested. The first attempt made by the Touring Club of France in health directions was to insist on the sanitary reform of the hotels that tourists were likely to frequent. Hotels that put in a proper system of drainage and furnished their rooms in a wholesome manner were allowed to call themselves Touring Club hotels. Here the thick carpets spread over the whole room and permanently fastened down, the heavy window drapings, and voluminous bed-hangings were all abolished. The paper in a Touring Club hotel is stripped off the walls and washable paint or distemper is employed instead. The floors are wood blocks polished with beeswax, or are laid with tiles. A small rug or two that can be lifted away and shaken alone is allowed on the floor. The numerous culture grounds for infective material provided by the old-fashioned manner of furnishing hotel rooms are thus done away with. Plenty of light and every facility for cleaning are provided, and in some cases now the angles between the walls and the floor and ceiling are being rounded off, so that these havens of dust will soon exist no more. The members of the Touring Club are provided with regular forms, so that they can send complaints to the central office if any hotel fails to keep the rules laid down. These rules relate not only to sanitation but also to the charges. If a traveller is overcharged he need not incur the unpleasantness of a dispute with the landlord. He need only insist on a detailed receipt for the payment which he has made. This he sends to the central office, and if he has been overcharged he will not have to wait long before the unjust surplus is returned to him. Agreements have been signed between the Touring Club of France with more than 3000 hotels, not only in France but in many other countries. Here the tourist will find the best sanitary conditions available, and will not have to pay more than the Touring Club tariff. Of late, in regard to this control exercised over hotels, a new and very interesting departure has been made. The gastronomic tourist has gained a hearing. With the increasing facilities of travel there is an unfortunate tendency to build hotels all over Europe on almost identically the same model. The menus of the meals are always in the same style, and local characteristics are being effaced by the general European assimilation. British and American travellers, by reason of their ignorance of the gastronomic arts, are largely responsible for the deterioration of the cooking, especially in the first-class hotels. The Touring Club is making investigations and offering prizes to those hotels which maintain the local traditions, which persist in cooking the dishes for which the town or province is renowned, even if a foreigner cannot appreciate them. When the best and most artistic samples of culinary art are looked upon with suspicion by the ignorant, or refused by the dyspeptic, the native chef is apt to lose heart, and so clearly had this become the case that the best traditions of French cooking were in danger. Now the Touring Club is trying to save the situation, and the connoisseur may still expect to find dishes capable of satisfying an experienced palate. After thus seeking to improve the hotels, the Touring Club exercises its great influence to maintain the roads by which all the beautiful parts of the country can be reached. It sees to it that there shall be a popular outcry raised if a natural or artistic beauty-spot is likely to be destroyed or spoilt in any way. But more than that, it watches over the forests that they shall not be uselessly cut down, that likely spots shall be planted with trees, that the beauty of sites shall be improved by suitable verdure or timber, and that the climate shall not suffer for want of sufficient woodland. All this is done by the exercise of personal influence and persuasion, by publications, by the distribution of prizes, and by the aid of subventions. Altogether the Touring Club of France has spent more than £100,000 in this public service, a service which does so much to facilitate that form of travelling called touring. This, we take it, is holiday travelling, and the holiday is essentially a health institution. The work of the Touring Club is the work of preventive medicine, for it facilitates the relaxation on which health so much depends; and, by the sanitary control of hotels, it seeks to dissipate those dangers that used to be associated with travelling and hotel life.

"THE FATE OF ICARUS."

"BYRON'S 'Mountain Spirit' (writes an Italian correspondent) might be credited with a 'sombre acquiescence' in the fate of poor Chavez were it to act as a deterrent to all future aviators in daring to 'molest her ancient, solitary reign.' But that grim satisfaction will be denied her. Other attempts will follow till the flight over the Alps will in turn be surpassed, and Chavez's feat (who knows?) be eclipsed by another, and less tragic, flight over the Andes of his native Peru. Meanwhile, the company of competing aviators at Milan were well inspired to suspend operations out of respect to their young rival's memory, for a more pathetic extinction of a career bright with promise has rarely been put on record. To have out-soared all competitors of all nationalities, to have earned the enthusiastic applause of the world, and the Rabelaisian title of 'Astrophil,' with the motto 'Quo non ascendam?' to have reached an altitude of 2680 metres, and to have succumbed to a fall of barely 20, surely this must have induced a moral revulsion, a 'heart failure,' which explains the nervous collapse which frustrated all the skill and care of the numerous consultants gathered round his bed. True, the surgical lesions were grave; not more so, however, if not indeed less, than those from which many a victim of a railway accident has recovered. But the experienced head of the medical clinique at Turin, the Senator Professor Bozzolo, entertained from the first a prognosis more than doubtful, remarking to a colleague as he left the patient's private room in the hospital at Domodossolo, 'I fear the diffused nervous shock is causing the ominous prostration. Neither the consultants in immediate charge of the case nor I myself have been able to localise any seat of disturbance.' Later, Professor Bozzolo

dictated the following bulletin: 'Considerable general depression, with tendency to drowsiness consequent on a restless night and increased since yesterday. Pulse at a high rate of frequency, 134; respiration, 34; temperature, 37° C. *Prognostico assai riservato* (prognosis very reserved.)' Every effort was expended towards saving the brave young soul, whose 'will to live' (the analogue in the physical, of the 'will to believe' in the spiritual, sphere) was a distinct clinical asset; but *Dis aliter visum*. Reviving for a time, under the inhalation of oxygen, of which 600 litres were consumed from first to last, he met each visit with a smile and seemed more concerned with the trouble he was giving than with his own sufferings. At last delirium supervened, in the course of which he was heard to murmur incoherently, the only expressions to be distinctly made out being, 'Ah! ..... *la montagne* ..... la montagne!' And so, having already received the last consolations of the Church at the hands of the good canonico Colcati, he glided away, in the words of John Tyndall, 'like a streak of morning cloud, into the infinite azure of the past.'"

INTESTINAL OBSTRUCTION DUE TO A FOREIGN BODY IN THE ABDOMEN, PRESUMABLY INTRODUCED THROUGH A PERFORATION IN THE UTERUS.

IN the *New York Medical Journal* of Sept. 17th Dr. Henry Roth has reported a case of intestinal obstruction due to an extraordinary cause—a foreign body in the peritoneal cavity which was apparently introduced through a perforation made in the uterus in the induction of abortion. A single woman, aged 24 years, was admitted into hospital with the following history on May 11th, 1908. Three weeks previously she had an attack of abdominal cramps and vomiting which lasted about eight hours. She remained well for a week, and then a similar attack occurred which lasted 24 hours. She again remained well until May 10th, the day before admission, when, whilst walking in the street, she was seized with severe abdominal pain and vomiting. The pain was more severe than before, and compelled her to take to her bed. At first the pain was all over the abdomen, but gradually it became most marked in the right lower quadrant. She vomited repeatedly, and on the following day suffered intensely from thirst, and was unable to retain even small quantities of water. In spite of the repeated administration of cathartics and enemata the bowels did not act. On examination the abdomen was found moderately distended; rigidity was most marked in the right lower quadrant. There was considerable tenderness over the lower part of the abdomen, and this was most marked on the right of the umbilicus. No mass was palpable. The temperature was 101° F., the pulse was 80, and the respirations were 16. The pain was observed to be paroxysmal, coming on about every ten minutes. In view of the history of two similar attacks in three weeks and the signs, acute appendicitis was diagnosed, but in consequence of the paroxysmal cramp-like pains the possibility of intestinal obstruction was not negatived. Laparotomy was at once performed, about 36 hours after the onset of the pain. The incision was made on the right side and on opening the peritoneum much clear serum escaped. Digital exploration revealed a cord-like structure running from the right side downwards towards the median line and attached to a mass of intestine which it constricted. The structure proved to be omentum and on separating it and withdrawing it from the abdomen a body about 2½ inches long and ¼ inch wide was brought out. This proved to be a pledget of absorbent cotton discoloured by blood. Further examination revealed two loops of ileum adherent at the mesenteric borders. The adhesions were broad and firm and required ligation before division. In the midst of these adhesions more cotton was found and removed. Part of the omentum and the vermiform appendix were removed. The question arose, How did the cotton reach the peritoneal cavity? As laparotomy had not previously been performed, perforation of the uterus in the production of abortion was suspected. The pelvic organs were therefore carefully examined. All that could be found was a small indurated area in the lower part of the posterior wall of the uterus. The abdominal incision was closed without drainage and recovery was uneventful. After the operation the patient admitted that she had had several abortions induced, the first about two years previously and the last on March 28th, 1908, when she was about two months pregnant, about six weeks before the onset of the present illness. No unusual pain or other symptoms followed the abortion. The last menstruation occurred about two weeks before admission. In most cases in which foreign bodies have been found in the peritoneal cavity they have been left there accidentally in the course of operations. In this case the cotton was probably introduced on a uterine sound or forceps which perforated the uterus. A. P. Heineck, by an exhaustive search of medical literature from 1895 to 1907, collected 160 cases of perforation of the uterus during intra-uterine instrumentation. In 26 the object was to induce abortion. He found that perforation could occur with startling ease even in the hands of clever operators. He disagreed with those who believed that the accident was not followed by alarming symptoms. Shock, hæmorrhage, injury of viscera, infection, prolapse of omentum or intestine, with or without strangulation, were the immediate causes of danger. Several cases have been recorded in which bougies were introduced into the abdomen through a perforation in the uterus in the induction of abortion and were later found when laparotomy became necessary and removed.

THE RIGHT TO EFFICIENT VENTILATION AT SEA.

A VERY important decision has been given by Judge Rentoul in the City of London Court. Returning from South Africa, two passengers complained that their cabin had no ventilation and paid £4 12*s*. 2*d*. to occupy another cabin, contending that "a cabin without a fan was quite intolerable." On the other hand, the Union Castle Mail Steamship Co. in their booklet state that "a complete system of ventilation had been adopted, and that electricity was brought to bear on the cabins, saloons, &c., by the adoption of a large number of electric fans." Judge Rentoul said that anybody reading the booklet would think all the cabins had electric fans in them, and as the discarded cabin had no fan he gave the verdict in favour of the passenger, and ordered that the money paid to ensure a change of cabins should be restored. So far so good, and it is something to know that the law can be invoked to secure the execution of promises made in regard to the ventilation of the cabins passengers have to occupy on board ships. But unfortunately ignorance in regard to ventilation is so profound that it is not difficult to satisfy the public with a sham and cheap pretence of its benefits. Whether the ship in question, has or has not "a complete system of ventilation" is a matter on which we could not possibly express an opinion without first very carefully inspecting the ship herself. If she has, then she differs from most other ships afloat. Much as the question of ventilation has been neglected on shore, it is still more behind the exigencies of modern scientific requirements at sea. All the talk of fans in the case just tried is evidence of the prevailing ignorance. There seems to have been an impression that a fan has something to do with

ventilation when, instead of being held in a lady's hand, it is attached to an electric wire. On shore, as well as at sea, an electric fan is sometimes placed on the ceiling of a restaurant or of a railway dining car, and when it whirls round it produces a sensation of coolness. But what has this to do with ventilation? From the bacteriological point of view such a mechanical toy does not improve the situation. On the contrary, by propelling the air violently on the surrounding furniture, floor, and people, it lifts up dust and causes us to breathe a larger quantity of dirt and its accompanying microbes than we should have done if the air had been left still. Ventilation does not consist of churning up the air. Fresh air is not manufactured on the same principle as fresh butter Nor does ventilation consist of making a draught. Draughts destroy ventilation, because those who suffer from draughts. and they are many, proceed to close the ventilator at the first opportunity. The ideal ventilation consists of the introduction into and extraction of air from an inhabited place, house, assembly hall, theatre, railway carriage, saloon or cabin of a ship, in such a manner as to be imperceptible to the persons breathing that air. The text-books state that for such air to be pure the supply must amount to one cubic foot per second per adult. On the other hand, so that this air-supply should not cause a nuisance, it must not travel through the place ventilated at a greater speed than three feet per second. That is the standard, and short of that standard it is a mere delusion to talk of "a complete system of ventilation." If these rules have been successfully applied on board any ship we hope the owners of that ship will allow us to visit her and to describe how this most difficult problem has been solved.

HYPERSOMNIA.

IN an interesting paper published in the *Revue de Médecine* of Sept. 10th Dr. Albert Salmon of Florence discusses certain abnormalities of the function of sleep. He differentiates hypersomnia, which is an increase in normal sleep, from somnolence, apathy, and torpor, such as occur in cerebral tumours, in cerebral œdema, and in grave intoxications, and from the drowsiness which occurs in old people. He accepts in part the toxic theory of normal sleep—viz., that it results from the action of the products of metabolism produced during waking activity; but he denies that this toxic action is exerted upon the nerve cells and suggests that the toxic products are neutralised by certain glands with internal secretions, which form also specific hormones exerting a reparative influence upon the nerve structures. He believes that the pituitary body is specially closely related to the function of sleep, since hypersomnia is one of the most marked characteristics of affections of that structure. Hypersomnia depends generally upon an exaggerated action of the same causes which induce normal sleep, the chief being intoxications. Dr. Salmon maintains that mild intoxications lead to an increased function of the pituitary body or other glands concerned, while more profound degrees of intoxication may lead to actual poisoning of the nerve cells, and eventually to insomnia. Hypersomnia occurs in mild degrees of insufficiency of the thyroid, and in association with defects in the functional activity of the genital glands. It also occurs in the slow intoxications of gastric, hepatic, intestinal, and renal origin, and sometimes in association with obesity and diabetes. Influenza is often accompanied by a considerable increase of sleep, which gives place during convalescence to deficient sleep or to insomnia. It also occurs in cerebral syphilis. In cerebral tumours, as in all cerebral lesions which lead to increased intracranial pressure, there is a condition of somnolence or torpor, but not a true hypersomnia. Tumours of the base, on the other hand, especially those involving the pituitary body or its neighbourhood, give rise to an actual hypersomnia. A similar exaggeration of the function of sleep occurs in mountain sickness, and so imperative may be the desire to sleep that the patients sleep against their will, even though they know that their sleep will predispose them to death. A similar exaggeration occurs in workers in compressed air, after insolation, and after epileptic seizures. In all these cases it is associated with cerebral congestion. Hypersomnia also occurs in connexion with certain diseases of the nose, especially with adenoid vegetations. This is explained by Dr. Salmon as being possibly due to over-activity of a gland in the posterior pharyngeal region having the anatomical characters of the pituitary body, which has been described by Civalleri. Its existence has been confirmed by Kilian, Erdheim, and other observers. A similar condition of hypersomnia is described in connexion with inflammation of the sphenoidal sinuses. In regard to the treatment of hypersomnia Dr. Salmon advises opotherapy in cases due to defects of the thyroid, pituitary, and other glands, attention to the diet in cases due to gastric, intestinal, hepatic, or renal defects, and surgical treatment in those due to nasal affections. Although some of his opinions are somewhat speculative in character, his observations are of considerable interest and should serve to direct attention to the disturbances of sleep other than insomnia, which have hitherto, perhaps, received less attention than their importance warrants.

THE LONDON MEDICAL EXHIBITION.

THE exhibits presented to view at the London Medical Exhibition, which was held this week in the Horticultural Hall, Vincent-square, Westminster, were of distinct interest to medical men, and each year shows an advance on the previous one in regard to the real medical character of the demonstration. Even many of the "side-lines" were of scientific interest, while the progress of pharmacology and therapeutics was abundantly illustrated at the various stalls of well-known distinguished firms and makers of fine pharmacological and therapeutic products. It was evident on all sides how earnestly the pharmacist is working for not only the chemical but also for the physiological standardisation of medicaments. Vaccines and the products of serum therapy were a feature, and there was also an interesting display of special foods, lighting and heating appliances, balneological appurtenances, and so forth. The exhibition has evidently become of genuine interest to the members of the profession, and judging from the increasing attendance of medical men and others connected with the healing art, the annual event must now be counted of importance, while it serves very well to refresh the memory with the rapid advances which pharmacy and pharmacology are making. The visitor will find it hard to go away without carrying off some information of value in his professional work.

FACTS AND PROBLEMS CONCERNING RABIES.

A USEFUL monograph on the subject of rabies has just been written by Dr. A. M. Stimson.[1] He points out that there are many points about the pathology of rabies that require elucidation. The Negri bodies appear to be specific for rabies, but the determination of their exact significance and their relations to somewhat similar bodies found in other diseases is still a problem and a most important one. Until these problems are settled our ideas concerning immunity must necessarily be vague. It is known, however, that artificial immunity can be conferred during the usual incubation period, and this knowledge has been of

[1] Bulletin No. 65, United States Public Health and Marine Hospital Service, Washington, D.C. (1910), pp. 90.

great service. The possibilities of antirabic serum have not been exhausted by trial. It deserves further investigation, but our present data do not warrant us to expect very much benefit from this source. The treatment of rabies by means of drugs has received but little attention within recent years, owing to the discouraging outcome of the earlier attempts at treatment. But the balance of evidence now suggests the protozoan nature of rabies, and in view of the fact that certain protozoan infections are amenable to cure by specific drugs this line of research now shows promise of yielding better results than was formerly the case, particularly as regards the action of certain drugs upon the parasite itself. Administration of drugs by the intraspinal method should not be neglected. It is desirable, further, that attempts should be made to improve upon the methods of immunising exposed persons in order to eliminate the small percentage of failures. Dr. Stimson points out that the eradication of rabies could be effected in other countries, as has been done in England, by preventing rabid dogs from biting other animals. The prevention of the disease rests entirely with the public and depends upon a single definite measure. Otherwise the patient work of "patching a bad job" and the slow searching out of better "patches" must continue, and more experimental animals must be sacrificed for the protection of human life. The bulletin contains chapters devoted to the literature and bibliography of rabies, its distribution, pathology, etiology, symptoms, diagnosis, and treatment, together with a section on immunity and suppressive measures.

MIGUEL BOMBARDA.

THE news that Professor Miguel Bombarda has been assassinated will come as a severe shock to the medical profession, but this loss will be more especially felt by those who had the good fortune to attend the Fifteenth International Congress of Medicine, which met at Lisbon in April, 1906. It will be remembered that Professor Bombarda was the general secretary of the Congress and that never before had a Congress been better organised. Describing the conclusion of the Congress and writing under the impression of the scene, our correspondent said: "As Dr. Bombarda and the President of the Congress stepped off the platform they were surrounded by numerous members eager to grasp their hands and to embrace them. Not a few, especially the Portuguese members, fell into each other's arms and indulged in many wild and excited manifestations of their joy at finding that the Congress had proved so complete a success. Loud were the shouts, the laughter, the cheers that accompanied the President and the general secretary as they struggled through the excited and grateful crowd from the hall to their private office. The Congress certainly ended joyfully. Everybody seemed pleased and happy." These few lines reflect the impression made at the time upon the members of the Congress, while medical journalists have intimate reason for regretting the loss of Professor Bombarda. Not only did he organise the International Medical Congress, but he also provided every facility for the meeting at Lisbon, two days before the Congress, of the General Assembly of the International Association of the Medical Press. He brought Councillor Abel d'Andrade, Director-General of Public Instruction, as representing the Portuguese Government, to inaugurate the meeting of the delegates of the medical press, and gave the press representatives the most cordial reception. The position he held in the medical profession lent him the necessary influence to organise with success such a great national effort as that of receiving worthily a large international scientific congress. In such matters, however, personal prestige does not suffice, it must be accompanied with the genius of organisation. This Professor Bombarda possessed to an exceptional degree, and the late King Carlos so well appreciated the fact that, at the close of the Congress, he conferred on its general secretary the broad lilac ribbon, the gold chain, and crimson cross of the Grand Cross of the Order of Santiago. Now an assassin, a madman it is said, has struck down one of the most sympathetic and distinguished members of the Portuguese medical profession. According to one account the aggressor was one of Professor Bombarda's former patients at the Rillafolles Hospital or Asylum, where he was the principal physician in charge, and the Professor's last act was to attempt to save his aggressor from injury at the hands of the attendants who came to rescue him. Others have seen in the crime great political significance.

THE EFFECT OF DIET ON THE RESISTANCE OF ANIMALS TO CERTAIN POISONS.

Dr. Reid Hunt has recently made a valuable contribution to our knowledge of the specific action of various foods, particularly of the effects of a restricted diet and of various diets upon the resistance of animals to certain poisons.[1] He points out that although the substitution of attention to diet for the use of drugs has led to highly successful results in the treatment of a number of diseases, notably those of the alimentary canal and diabetes mellitus, it can scarcely be said that even the theoretical basis for the choice of foods in health and disease has been laid. In other words, although there is a vast accumulation of accurate knowledge of foods from the dynamic and economic points of view, but little is known of their specific action. A number of clinical observations have already indicated that certain foods do possess a specific action. Thus certain cases of diabetes mellitus are much benefited by oatmeal, while beri-beri and pellagra are said to be closely associated and perhaps dependent upon the use of rice and maize. Dr. Hunt's earlier experiments showed some very striking alterations in the resistance of animals to certain poisons produced entirely by changes in diet, animals on certain diets being able to resist as much as 40 times the amount of certain poisons fatal to animals fed upon other diets. It seems possible that man is daily producing profound effects upon his resisting power to poisons and diseases, and the experiments so far made, although incomplete, may have value in suggesting new lines of research and new points of view for analysing some of the problems now vaguely referred to as "the resisting power of the individual," "constitution," "diathesis," and so forth. Dr. Hunt's recent work shows that a restricted diet increases the resistance of certain animals to acetonitrile. Guinea-pigs fed upon a limited diet excrete a smaller percentage of the cyanogen of acetonitrile as sulphocyanate than do those upon an unrestricted diet. Dextrose, oatmeal, liver, and kidney greatly increase the resistance of mice to acetonitrile, their effect being similar in this respect to the administration of thyroid glands. This effect is probably due in part to a specific action of the diet upon the thyroid gland and thus affords an illustration of how an internal secretion may be modified in a definite manner by diet. It was also found that diet may exert a marked effect upon the reaction of animals to iodine compounds. The experiments showed that it is possible to classify a number of foods as to whether they affect the organism of the mouse in the same way as thyroid or in the opposite way. Oatmeal, liver, kidney, dextrose, and certain kinds of wheat bread belong to the former class, and milk and eggs to the latter. It is probable that the human organism reacts in the same way, and it is suggestive that the great value of eggs and milk

[1] Bulletin No. 69, Hygienic Laboratory, United States Public Health and Marine Hospital Service, Washington, D.C., 1910, pp. 93.

in the treatment of exophthalmic goitre, and the advisability of eliminating sweets in this disease have already been demonstrated. These experiments are of interest in connexion with the efforts made by Ehrlich to find drugs having special affinities for certain organs—drugs which are neurotropic, lipotropic, thyreotropic, &c. Dr. Hunt's work suggests that it is possible by diet to modify organs so that they may more readily take up certain drugs. Several glands, notably the prostate, ovaries, and testes, have an effect upon the resistance of animals to poisons similar to, but much less marked than, that of the thyroid gland. The thymus, parathyroid, and suprarenals have either no effect or an effect opposite to that of the thyroid. The resistance of animals to certain poisons varies with the season, and in some cases seems to depend upon the seasonal variations of the thyroid.

MR. PLEWIS'S TASTE.

A Mr. Plewis, a member of the Medway board of guardians, at a meeting on August 23rd (according to the *Chatham, Rochester, and Gillingham News*), contributed to the discussion of the overcrowding of the Barming Lunatic Asylum the following vulgar remark: "I often wonder whether there would be so many cases over there but for the fees." Dr. Hugh Woods, the secretary of the London and Counties Medical Protection Society, thereupon addressed to the chairman of the board the following letter:—

31, Craven-street, Strand, London, W.C.,
27th August, 1910.

Dear Sir,—My attention has been called to newspaper reports, according to which a Mr. Plewis is credited with having suggested that lunatics were sent to the asylum by medical men in unsuitable cases for the sake of the fees.

This is grossly offensive, and I believe untrue and slanderous. May I therefore respectfully suggest that Mr. Plewis should be called on to substantiate or withdraw his odious charges with the same publicity as has been given to them by him. Yours faithfully,

HUGH WOODS.

The chairman does not seem to have pressed upon the unwilling Mr. Plewis the obligatory and proper course suggested to him by Dr. Woods, but rather to have complained that he himself was subjected to some annoyance "because people have spoken to him and expressed an opinion that their friends ought not to be in the asylum. For that reason he thought that Mr. Plewis should withdraw the statement to save any further annoyance." Mr. Plewis withdrew his statement, adding with complete bad taste "that so far as their own medical officer was concerned he believed he was above anything of the sort implied in the letter." If guardians are deprived of much of their power and discretion in a reformed Poor-law, they will have suffered largely for the manners of a few of their number.

ACTIVE LOBAR COLLAPSE OF THE LUNG.

WE publish in this week's issue of THE LANCET an interesting and suggestive paper by Dr. William Pasteur on Active Lobar Collapse of the Lung after Abdominal Operations. He gives details of five cases presenting a characteristic group of symptoms and physical signs which he interprets as due to an active deflation of large areas of a lung following on reflex inhibition of the movements of the diaphragm on that side. The symptoms in question are usually, but not invariably, sudden in their onset. They consist of dyspnœa, cyanosis, and pain. Cough, though often present, is not a marked feature in uncomplicated cases. Greenish expectoration occurs, but rusty sputum has not been observed. The physical signs are loss of movement on the affected side of the chest with exaggeration on the healthy side, and dulness at the base of the lung, with weak or absent breath sounds, or sometimes weak tubular breathing. A peculiar and notable sign is shifting of the heart's impulse towards the affected side. The symptoms, although grave, usually last for a brief period, and the affected lung shows evidence of returning function within a few days. The analogies presented by these clinical features with those of massive collapse of the lung occurring in association with respiratory paralysis in diphtheria and other conditions, which have been studied by Dr. Pasteur in his previous work upon active collapse of the lung, lead him to refer these cases to a similar explanation, and in view of the evidence he brings forward it is difficult to resist his conclusions. There can be little doubt, as he suggests, that cases of this character have in the past been referred to the category of post-anæsthetic pneumonia. His interesting observations should lead to a more careful study of the lung conditions which occur after operations and after anæsthetics. We cordially endorse his plea that physicians should be afforded an earlier opportunity of observing these cases by their surgical colleagues than is the case at present.

THE DRY SEPTEMBER.

SEVERAL of the Septembers of recent years have brought weather differing very considerably from the average. Some have been abnormally hot, and some exceptionally bright, but the month which has just elapsed has been chiefly remarkable for its dryness. The only thing worthy of note in its temperature was the absence of heat during the afternoons, when it was rare for the thermometer to rise to the ordinary figure for the time of year. As regards sunshine we have had many splendid days, and in a few scattered localities the total number of hours exceeded the average, but generally there was a deficit, amounting at some of the observing stations to about an hour per day. The records of the Meteorological Office prove that it is extremely seldom that a month gives less rain than the average over the whole of the kingdom, but during last month there was not only a great deficit throughout the entire country but the number of days on which rain was experienced was also very small. In England generally there was no single fall measuring as much as a tenth of an inch except in the eastern and south-eastern counties and in one or two districts in the midlands about the middle of the month. The driest regions were the southern and south-western counties of England and some parts of Wales. At Bournemouth and Bath the respective totals were 0·11 inch and 0·15 inch, and 28 days were quite rainless. At Weymouth there was only 0·15 inch, falling on three days, and at Pembroke 0·11 inch, falling on seven days. Other notable illustrations of the unusual lack of rain were afforded by Manchester, where rain fell on only four days and yielded no more than 0·18 inch, and at Buxton, where the aggregate was 0·24 inch against an average of 3·17 inches. In London the 0·55 inch was, with a single exception, the lowest September total recorded since the observations began in 1871. The exception occurred in 1898, when the month gave no more than 0·31 inch. September of 1907 was, however, very nearly as dry as last month, the fall being 0·58 inch divided between eight days.

THE SCOPE OF A PHARMACOPŒIA.

IN the *Bulletin of the American Pharmaceutical Association* for September Dr. S. Solis Cohen contributes a thoughtful article on the scope of a pharmacopœia. The modern school of pharmacologists advocates the exclusion of a large number of drugs the value of which has not been demonstrated by laboratory experiments. But Dr. Cohen points out that the pharmacopœia is not a work on therapeutics, and the description of a drug in its pages should not be taken as evidence that the therapeutic value of the drug has been definitely established. A drug should not be condemned because certain workers are unable to obtain satisfactory

results from its use. Dr. Cohen mentions cactus grandiflorus as an instance of a drug which has been pronounced to be pharmacologically inert by some writers as the result of experimental tests, while, on the other hand, another good authority maintains that it possesses high clinical value when carefully prepared and properly used in suitable cases. In deciding on the inclusion of a new drug or the exclusion of an old one a general consensus of opinion among practising physicians must be the criterion. It has been urged that when a drug is fairly well represented by an active constituent the latter should be retained to the exclusion of the crude drug and its galenical preparations. Complaint has also been made against the inclusion of too many remedies of one therapeutic class. Dr. Cohen holds the opinion that it would be unsafe for physicians to limit their official armamentarium. Thus, strophanthus and adonis should find a place equally with digitalis; opium, morphine, and codeine should all be officially recognised, and the useful salts of cinchona side by side with the drug itself. There are cases in which continued medication is necessary for a long period when it is desirable to vary that medication. In order to be of use to the whole profession it is permissible and even necessary to include in a pharmacopœia many drugs of similar action and many preparations of one drug. Active principles should not displace crude drugs and their galenical preparations, unless physicians in general agree that the active principle is the only necessary or desirable preparation.

Mr. Charters J. Symonds will deliver the opening address on "The Treatment of Chronic Abscess of Bone by Means of Metal Drains," illustrated by patients, preparations, and radiograms, at the Medical Society of London, on Monday, Oct. 10th, at 8 P.M. A discussion, to be opened by Sir W. Watson Cheyne and Mr. A. E. Barker, will follow.

THE first Hunterian Society's lecture will be delivered at the London Institution, Finsbury Circus, E.C., on Wednesday, Oct. 12th, at 8.30 P.M., by Dr. H. D. Rolleston, on "Acute Arthritis of Doubtful Origin."

THE Harveian Oration will be delivered by Dr. H. B. Donkin at the Royal College of Physicians of London, at 4 o'clock precisely, on Tuesday, Oct. 18th.

THE annual dinner of the London School of Tropical Medicine will be held on Friday, Oct. 14th, at the Hotel Savoy, under the presidency of Mr. James Cantlie.

PRESENTATIONS TO MEDICAL MEN.—On Sept. 26th Mr. J. H. Marsh, medical officer of health of Macclesfield, was the recipient of a silver-mounted walking-stick and leather letter case from the children of Prestbury, Lancashire. A short time ago a severe epidemic of scarlet fever passed through Prestbury, and under an arrangement between the rural sanitary authorities of Prestbury and the Macclesfield corporation the cases were removed for treatment to the borough isolation hospital at Macclesfield. So impressed were the children with the kind treatment which they received at the hospital under the direction of Mr. Marsh that on their return home they decided to show their love for their medical attendant by making him a presentation. To Mrs. Marsh they gave a handbag and a basket of flowers.—Dr. J. R. Kaye, county medical officer of health for the West Riding of Yorks, and honorary secretary and treasurer for the past 17 years of the Yorkshire branch of the Incorporated Society of Medical Officers of Health, was on Sept. 30th presented with a silver epergne for fruits and flowers by the members of the society. The presentation, which was in connexion with the silver wedding of Dr. Kaye, was made by Dr. J. S. Cameron (Leeds) at the County Hall, Wakefield.

EHRLICH-HATA "606."

BY FLEET-SURGEON W. E. HOME, R.N.

A NOTE by the Berlin correspondent of THE LANCET last July[1] gave an account of the historic meeting of the Berlin Medical Society on June 22nd, when Dr. Wechselmann and the others announced the wonderful results they had been obtaining with Ehrlich's "Hata preparation" in the treatment of syphilis. Being a naval surgeon I was deeply interested, and as I could get to Germany, and was, by the kindness of the Editor of THE LANCET, provided with an introduction to Dr. Wechselmann, I went to see him. He is the head of the division for skin diseases (which includes venereal diseases) in the great (3000 beds) Rudolph Virchow Hospital in Berlin. *Inter alia*, he has long been known for research work done on the protozoa. Before detailing what I managed to pick up about the astonishing effectiveness of this medicine, I think it will be well for the benefit of other general practitioners like myself, who learnt their pathology a good while ago and do not know how the Hata-preparation was discovered nor how it acts, to briefly abstract a paper on this subject by Professor Ehrlich. He gave me a copy when I was in Frankfort, and I hope he will forgive the use to which I put it. It is termed "The Chemotherapy of Infectious Diseases," and was read, I suppose, about August, 1909.[2]

Professor Ehrlich on the Exact Treatment of Infectious Diseases.

"There are two ways of treating disease, one by immunising the patient, immuno-therapy, the other by curing with drugs, chemotherapy. These methods are at certain important points the same; thus the production of antibodies is of the greatest value in each system; still, their differences are more important. Immuno-therapy concerns itself only with the antibodies, which owe their strongly marked specificity to their individual origins. These antibodies direct themselves exclusively against the bacteria and their poisons, to the protoplasm of the patient they do no harm; that is why immuno-therapy is the ideal, the perfect treatment. Without damage to the body it attacks the parasites only. Every sensible man will try to secure for his patient an immunity, active or passive, if immunity be attainable. But in the class of diseases caused by protozoa, malaria, tick fever, and the others, the desired production of antibodies does not occur. Their clinical course shows that this curative reaction of the organism is hindered by the nature of the parasites themselves, so we have to go on killing them with chemical substances, just as we have been doing in the past with quinine, mercury, iodides, and atoyxl. All such chemical substances are poisons; unlike the antibodies, they attack also the patient's organs and tissues and may do him harm even in the doses required to produce their therapeutic effect. Such considerations urged me to make the thorough and systematic examination of this department of therapeutics to which in the last few years I have devoted myself.

In ordinary chemistry the first principle is, *Corpora non agunt nisi soluta;* on the contrary, in chemotherapy, the first principle is, *Corpora non agunt nisi fixata.* That is to say, that unless a drug can combine with the bacteria it cannot kill them; such drugs are called parasitotropic, they attack the parasites. But being poisonous, they also attack the organs of the body, and so are termed organotropic The practical utility of the drug depends on the relation which these activities bear to one another. The organotropic effect should be low, the parasitotropic high, if the drug is to be of any use to us.

The next thing was to find out how the drugs became fixed to the cells, and the most significant ideas came from the study of drug-resisting strains of trypanosomata. Thousands of drugs had been tried against trypanosomes, and those that had curative results fell into three groups:—1. Arsenic group, arsenious acid, then atoxyl, and later the other substitution products of arsenobenzol—viz., arsacetin, and arsenophenylglycol. 2. Azo-stains, trypan red, blue, and violet. 3. Basic stains, parafuchsin, methyl violet, pyronin.

---

[1] THE LANCET, July 9th, 1910, p. 136.

[2] Chemotherapie von Infektionskrankheiten v. Professor Ehrlich, Zeitschrift für Aertzliche Fortbildung, No. 23, 1909. Jena, Fischer.

Strains of trypanosomes can be grown to resist either of these groups. When I examined this more exactly (and it was convenient to work with a strain resistant to atoxyl and arsacetin) I began to see there must be some special arrangements with affinity for particular chemical groups to fix them to the cell. These special arrangements, these bonds, I name chemoceptors. The chemoceptors of the parasite which fix arsenic, and which I call arsenoceptors, unite trivalent arsenic (arsenic as in arsenious acid) to the cell. They do not disappear from an arsenic resisting strain, but only become chemically altered so as to have less affinity for arsenic. And now the arsenic must be present in relatively considerable excess before it can unite with the parasites in such quantity as ultimately to destroy them. Under the microscope these drugs are seen to affect the parasites, causing paralyses, slower movements, or swelling, and in testing the drugs we have to employ them in very various concentrations, and we must also try them on infected animals. In the laboratory examination of each drug there are four possible events.

1. No effect *in vitro*, none *in vivo*. Then neither the parasite nor the body has chemoceptors with affinity for this drug, which is therefore neither parasitotropic nor organotropic.

2. Marked effect *in vitro*, none or little *in vivo*. (This is the action of sublimate on anthrax.) Methylene blue 1/6,000,000 is effective against the spirillum of relapsing fever *in vitro;* used 500 times as strong it produces no effect *in vivo* (Hata). This substance is markedly parasitotropic, but its organotropy [its affinity for the body cells] is so marked that *in vivo* none gets away to attack the parasites.

3. This is called the indirect effect. Nothing *in vitro*, good effect *in vivo*. (*a*) The drug inactive outside is within the body changed into a very active substance. Thus atoxyl, containing five-valent arsenic as arsenic acid, is in the body reduced to para-amido-phenylarsenious acid, trivalent, and that is readily fixed by the arsenoceptors. (*b*) The drug may have no evident effect on the life of the parasite, but may quite prevent its reproduction by some action on its chromatic substance. This race-sterilisation is of the utmost importance when it is with short-lived organisms like trypanosomes we are dealing.

4. Marked effect *in vitro*, even greater *in vivo*. Those parasites killed early, just after the injection, when dead awake an active formation of antibodies, which assist the action of the drug.

Four kinds of effect are also to be noted in the therapeutic results produced by these drugs on infected animals:—

1. No influence—no parasitotropy or organotropy markedly in excess.

2. Exacerbation of the disease. The substance is very little parasitotropic; indeed, as is usual in small doses, it stimulates the parasites. This occurs with methylene blue, not with arsenic. This result is often met by people working at cancer growth. It is called a contrary effect or Hata's phenomenon.

3. Therapia sterilisans convergens. This is a very common effect, that at which we aim. The parasites gradually decrease in geometrical progression.

4. Therapia sterilisans divergens (Browning's phenomenon). The parasites first increase before finally they disappear.

Now we return to our pharmacology and to the arsenic-resisting strains of trypanosomes. A race of trypanosomes resistant to atoxyl was not affected by the ordinary arseno-benzol derivatives, but we found arseno-phenylglycin which overcame their resistance, and in time we immunised them against this too. We had now two strains immune to arsenic, but each proved still susceptible to arsenobenzol derivatives, provided these had acetic acid in their molecules. So, besides their arsenoceptors, trypanosomes had aceticoceptors, by whose help they could be fixed to more arsenic and so destroyed. The drug was then attached to the trypanosome, not by one, but by several of its receptors (like a butterfly to a setting board by papers), and so I learned there were primary and secondary haptophores. The aceticoceptor is the primary haptophore which fixes the arsenic to the cell. If, then, we wish to use the arsenic group against a class of parasites by the methods of chemotherapy we can only succeed if we find the special suitable attachment, associate therewith the effective chemical group, and in this way make the specific attachment possible.

For the trypanosomata this is achieved through the aceticoceptors. Now the iodide of arsenobenzol which Bertheim prepared has no effect on trypanosomes in mice, but, as Rohl and Hata have shown, it kills spirilla in mice. Iodising the arsenobenzol nucleus has so reduced its power of fixing itself to trypanosomes that it reaches them in too small quantity to be deadly. But as for spirilla, the iodine enables the arsenobenzol to attach itself to them doubly, with increased effect. And so anyone who busies himself with chemotherapy must endeavour to find a chemoceptor which shall enable him to force his drug on the parasite concerned.

These advances should lead to great results. Already Hata, Kitasato's sterling pupil, has succeeded after long endeavour in finding amongst a great number of substances two preparations of Dr. Bertheim, No. 599 and No. 606, which are specially fatal to spirilla, and has cured mice of relapsing fever, and fowls of fowl-spirillosis. Rabbit syphilis also gives encouraging results. A large chancre full of spirilla yielded none the day after injection of the animal, and in two or three weeks was well, only a slight scar remaining.

So far I have dealt only with the first stage of the research, which decides whether a substance has therapeutic value and how it may be safely administered. Next, with great expense of time and material, from amongst all these we must choose the best. We may not be able to use a drug though it can cure; it may be too dangerous. The efficient dose may be 8/10ths or 9/10ths of the poisonous dose; 1/4th is as near as we dare go. [The fraction for "606" in rabbit syphilis is 1/7th to 1/10th. In man about 1/12th.—Trans.]

I have now completed my account of the labours of the school of chemical therapy. We had set ourselves exclusively to devise substances which we have sifted through innumerable experiments on animals. People feared we would flood the world with new remedies, but, after all, we have only recommended four—arsacetin, arsenophenylglycin, tryparosan, and the new "606," which Hata investigated.

Now that the work of the laboratory students is ended, a new and at least as difficult a study begins—the introduction of the new remedy into medical practice. Our first difficulty is that in man we cannot directly determine the maximum dose, but only learn it by slow and patient observation. Then men have idiosyncrasies towards about half the drugs we already know. From these animals are free. In relation to these strange and powerful drugs these susceptibilities of men may well be heightened. So the new drugs must only at first be used in well-managed hospitals and under the most patient, thorough, and continuous observation: with the person kept in bed, and all his organs and systems carefully examined. We must exclude all doubtful cases, people of extreme age, people with advanced disease, positive or doubtful history of previous arsenical treatment, special susceptibility to arsenic (which should be tested), retinal changes, and so on. Only after a great number of cases have been so scrutinised and reported on can the remedy be put at the disposal of the profession."

Clinical Employment of the Remedy.

The drug was first tested on man at Uchtspringe, under the direction of Dr. Alt, by two of his assistants, who in October or November, 1909, had 0·1 gramme (1½ grains) injected into themselves. The drug has been used continually ever since in increasing quantity and without disaster. This is largely due to Professor Ehrlich's preliminary work. Dr. Alt said in Berlin, on June 22nd, that the foundation work done by Ehrlich went so deep down there was nothing more required but care and to transfer to man with forethought what was known of its effects on animals. I could not hear in Germany of any disappointments. I was told in England—the story came from Aix—that the new preparation was so dangerous that its use had been forbidden in Germany. This was quite untrue, there never was such an order; there never was need for such an order. Every case is most exhaustively examined before treatment, special attention being given to the conditions of heart, urine, and retinæ. Retinitis and albuminuria are not absolute contra-indications. That depends on etiology. "606" has cured them when due to syphilis. The blood must be examined by the Wassermann reaction so that recovery may be gauged.[3] Every precaution is taken that no unwished result may occur, or that, occurring, it may give guidance so we may prevent it in future. Unwished results have, in fact, not occurred, so careful and complete were the rules Professor Ehrlich drew up for the first transfer

[3] The practitioner may do the Wassermann reaction with von Dungern's bedside apparatus (Merck).

to men of the experience gained by experiments with "606" on many kinds of animals. Besides, he trusted the remedy at first only to most expert and loyal physicians. It is urged that some new-born children succumbed after treatment. True, but their death is not the important thing to remember. Eight newborn children were in the hospital (Wechselmann), all obviously dying from pemphigus neonatorum. Three were treated by the old methods and all died, as had been forecast. With great anxiety, for the drug was new, the other five were injected. Of them, three indeed did die, but the astonishing, outstanding, illuminating fact is that the other two of these doomed infants, injected with the new remedy, contrary to any possible chance there would have been for them three months before, did recover.

As I saw the injection done it was prepared a little differently from that so well described by Mr. J. E. R. McDonagh.[4] But the technique varies between Frankfort and Berlin. I saw it done thus. In the first place everything is sterilised. The pale yellow "606" is shaken out of its glass capsule into a sterilised agate mortar and there rubbed up with some 10 to 15 minims of a 15 per cent. solution of caustic soda till it is all dissolved; a drop of phenolphthalein indicator is added, and next glacial acetic acid to neutralisation. This brings down a bright yellow fine precipitate, and all the contents of the mortar are washed into a test-tube which is centrifuged, the supernatant liquid is poured off, the precipitate mixed with 5 c.c. (℥i.) or so of normal saline solution and injected in suspension with a sterile syringe. The needle must have a large bore and must be particularly carefully wiped clean with sterile muslin before being used, to diminish the risk of skin necrosis. Women get 0·5 gramme or less, men 0·6 gramme or more. Women are now injected usually under the right mamma; men about the scapular angle. I should think the anterior injection more comfortable, as the patient does not want to lie on the place. The skin, clean already, is painted just before the injection with, I suppose from the colour, liquor iodi fortis half strength. The injection is subcutaneous, but intravenous injection is being considered more effective. The whole dose is able to attack the spirilla at once without the delay of waiting for absorption. The great fear is that the spirilla may, if slowly attacked, develop immunity. Hata found in rabbits that a fourth injection produced no additional effect. Further, intravenous injection causes no pain. The subcutaneous injection causes no trouble worth mentioning at the time; a few hours later pain and swelling begin, and quite often there may be an unimportant rise of temperature of 2° F. for a couple of days. Sometimes there is a necrosis, but that is rare. It is unimportant; I saw the positions of many injections with only two necroses, never an ulcer. The tendency is to increase the dose. If it be too small the Jarisch-Herxheimer reaction is noted—i.e., the exanthem deepens or brightens in colour before it disappears. If the roseola develops in two or three days that matters not, but if it appears a fortnight after injection the dose must be repeated. It is difficult for me, who was merely "walking the hospitals," to report on cases; besides, so many have been completely published it is almost unnecessary.

Case shown. "This man had a chancre here, two days ago he was injected. You see the chancre has healed." When a chancre occurs on the skin, if possible I, in my practice, always excise it, and, with luck, it heals by first intention. This saves the patient and his attendants trouble and time; but here is the sore healed, the glands are reduced and no roseola will follow, all by an injection of 9 grains of "606," a vastly superior therapeusis.

I saw an infant about August 23rd that to my inexperienced eye appeared ordinarily healthy. It had been dying a month before from congenital syphilis. July 20th, 0·02 gramme was injected. July 21st, Wassermann positive. August 3rd, repeated 0·02 gramme. August 18th, Wassermann negative. This treatment has only been in use ten months, but relapses do not seem to occur. We hope it kills all the spirilla, but malarial parasites do seem sometimes to hide in the spleen and escape quinine. It may be so here, we cannot know yet.

A woman was injected during pregnancy and her child showed no sign of syphilitic infection. Perhaps we shall be be able to do without the two years' quarantine before marriage. A man walked in. "This man was dying last April with ulcers of tonsils, uvula, and legs. He was injected and began at once to recover." Probably he got too small a dose as he was so weak, for he had been injected since, in June and August. He had lost nearly all the soft palate, but everything was healed up and he very grateful. So was a woman who appeared another day, having been injected five weeks before. Dr. Wechselmann demonstrated her chest now free of rash, though then quite covered. "Yes," she burst in, "blue-red spots all over it." She was delightedly grateful to her healer. Another case had beside him a painted model of his lesion as it was before his injection ten days ago. There was an ulcer on the palm of the left hand of the size of a crown-piece at the base of the second and third fingers, going deep at the edges. Now all was smooth and on one level, the scar being much the same colour it had been on the cast. Three days later I saw him again. The colour of the scar had faded; it was now shading off into the surrounding epidermis. A remarkable recovery in a fortnight.

A very bad lupus case was shown, injected four days previously; the crusts had now all fallen off without other treatment, and this in four days! Ulcers, too, due to breaking-down of gummata were unusually clean and flat. Their repair is said to be accelerated astonishingly. Local treatment consisted only of acetate of alumina compresses.

Staff-Surgeon Dr. Gennerich of the German Navy showed me two interesting recoveries from paralysis in his wards in the Naval Hospital at Kiel. One man with complete paralysis of the left side of the head and right side of the body, from gumma in the brain, injected yesterday could to-day move his leg and foot and also slightly his hand and fingers. Staff-Surgeon Gennerich had treated 30 cases, all with satisfactory results and with no undesirable complications. He finds larger doses up to 0·7 and 0·75 gramme suitable for young healthy men (Professor Ehrlich subsequently approved this). He also took the greatest trouble in the kindest way to make me thoroughly understand the principles and practice of "606" administration, for which I am very grateful.[5]

In Professor Ehrlich's waiting-room at Frankfort I found a dozen other doctors from Brazil, Holland, Belgium, and elsewhere. (In Dr. Wechselmann's clinique I had met others from Russia, Austria, and Hungary.) Professor Ehrlich's janitor told me that they had been besieged by people wanting the new remedy. I only noted one English name in the visitors' book, that of an Oxford professor. Some were much vexed when they found that there was none of the preparation to be had at the moment. I was the last to see the Professor, and only after an hour's wait. What a tax on his time! He allowed that the discovery of the new remedy was a direct outcome of the side-chain theory of immunity; confirmed what Dr. Gennerich had told me, that the amido group in the "606" molecule took, in curing, the place of complement, which was interesting; recommended intravenous injection; kindly gave me copies of some valuable papers by Hata and himself; and said that supplies at present were scanty, but it was hoped that by November the Höchst Farbwerke would be able to supply the popular demand for the Hata preparation. I then bowed myself out.

I see that it has been used in the Hamburg Tropical Disease School in the treatment of that other obstinate protozoal infection malarial fever from Mamory, in South America, by Dr. Nocht and Dr. Werner.[6] To each of five cases they gave 4½ grains, a very small dose. One case appeared to be cured; in three cases the parasites and fever disappeared for the time, but returned; while in the fifth case the number of the parasites only decreased. A speaker at the Berlin Medical Society on June 22nd stated that the drug had great effect in the healing of wounds. That I have not seen again stated since. Everyone who has any of the remedy wants it for his worst cases of syphilis, especially for those which resist mercury and iodides. It is thought too valuable for that purpose to be employed out of curiosity for anything else yet.

This seeking information about the new preparation was a memorable experience. And again it is a great pleasure to me to acknowledge the courtesy, the warmth of the welcome one gets from our German colleagues. The origin of Ehrlich-Hata "606" is a striking story of a research definitely planned to find a drug which should kill protozoal parasites without injuring their human host. That Ehrlich directed

his fellow-workers' efforts successfully in this task demands praise; that he then got it safely introduced into clinical medicine without disasters arousing suspicion demands our gratitude as well as wonder.

MEDICINE AND THE LAW.

Deaths after Operations and the Jurisdiction of the Coroner.

A QUESTION which may be described as being of some antiquity, but one not often discussed, was raised recently at an inquest held at the Royal Infirmary, Preston, upon the dead body of a man who had died after an operation had been performed upon him.[1] The evidence of the house surgeon, who had been for three years on the staff of the infirmary, was to the effect that the deceased was admitted suffering from intestinal obstruction; that an operation, if successfully performed, offered the only means possible by which life might be saved; that one was performed but did not save life, the man dying so soon after the operation that in the witness's opinion the death must be described as having been "accelerated" by it. Without the operation the man would have only survived for a few hours. Upon the replies thus given apparently the question was raised as to how far deaths following operations were, or should be, reported to the coroner from the infirmary, and the house surgeon very reasonably pointed out that if an inquest were to be held whenever a patient's death ensued within a few hours of an operation surgeons would naturally be deterred sometimes from performing operations which might, or might not, save life. The coroner and jury unfortunately seem to have resented a statement which for some reason they regarded as a threat, and the reason for which the coroner professed himself unable to understand, but the house surgeon pointed out the probable ill effects of publicity in such a case in causing the public to blame the surgeon for his lack of success and to regard operations with alarm. The coroner, in spite of this, expressed his own opinion that it was compulsory upon him to hold inquests upon persons dying in the circumstances described, owing to their deaths being "unnatural" within the meaning of the Coroners Act, 1887. In this we believe him to have been mistaken, and he would hardly have expressed such an opinion with confidence if he had considered some of the recent pronouncements upon a subject which, as we have said, is by no means a new one. We may point, for example, to the first or general report of the recent Departmental Committee upon the law relating to coroners, in paragraph 16 of which the question of deaths under anæsthetics is dealt with briefly. A recommendation is made that in such cases the death should be reported, but the coroner after inquiry should be enabled to dispense with an inquest when satisfied that due care and skill have been used. The committee does not seem to have thought it necessary to refer in its report to cases of death following recovery from the anæsthetic but accelerated, or suspected of being accelerated, by the operation itself. As to this the committee had before it the evidence of Mr. J. Brooke Little, a barrister of 30 years' standing, and a high authority upon the subject of coroners' law, upon which he was called to speak as an expert. He had it put to him definitely by Sir Horatio Shephard that under the words of the Coroners Act, 1887, a man who dies under an operation dies a violent death. The Act, as all will remember, refers to "either a violent or an unnatural death," but the word violent sufficiently brought the section to the mind of Mr. Brooke Little, who made no suggestion whatever that there was a legal obligation to inform the coroner on such occasions. His answer was, "I do not think that comes within the meaning of a violent death. The usual death certificate of a doctor is 'death from shock.' I think that is the general formula when an operation is being done and the patient dies," and he added as an example when asked whether it was not the unnatural form of stimulus which produced the shock, "You give the symptom, appendicitis, and the immediate cause of death you give as syncope from shock or heart failure, so that it would not be a violent death." The question relating to deaths under anæsthetics, as distinct from those accelerated by the operation, frequently recurred in the evidence of other witnesses before the committee, and we may refer to the opinion expressed by one of these, Mr. R. Henslowe Wellington, who spoke of the undesirable tendency of reports of inquests to cause alarm in the minds of the public as a reason for not holding them when patients die under an anæsthetic. This gentleman, whose experience as a coroner and writer upon coroners' law is considerable, had no such confidence as that of his colleague at Preston, even where deaths under anæsthetics were concerned. He gave it as his opinion that the law required an inquest, but he said that there was a difference of opinion among coroners on the subject, some holding inquests whenever such deaths were reported to them, and others not doing so if satisfied by inquiry that all care had been exercised. We have, however, cited enough authority to show that the coroner at Preston is almost certainly wrong in an interpretation of the law which differs from that of the great majority of his colleagues. The matter would have been settled long ago if coroners were liable to have their decisions on points of law submitted to the consideration of the High Court, and it might have desirable results if this were in some way to be provided for by statute. As it is, we do not understand that the Bill for amending the law relating to coroners introduced by Sir William Collins in the House of Commons touches the topic which we have discussed above. Clause 9 is designed to enable a coroner to dispense with an inquest if, after the inquiry for which the Bill affords facilities, "he is satisfied that the deceased died a natural death," but this would not affect the decision of a coroner who considered that all deaths accelerated by surgical operations were unnatural.

[1] THE LANCET, Oct. 1st, 1910, p. 1046.

Another Fatal Case of "Christian Science Healing."

At Urmston, near Manchester, recently an inquest was held upon the body of Walter Statham, a cashier, 53 years of age, who in May of the present year had been attended by a medical practitioner owing to the condition of one of his legs, and at that time had been willing to seek the advice of a surgeon. The surgeon in consultation, with the assent of Mr. Statham's medical adviser, had recommended amputation as necessary, but to this the patient refused to submit and subsequently discontinued all treatment and had recourse to "Christian Science" until his death, which took place on Sept. 25th. A "healer," William Pitfield by name, undertook the case for a consideration of 10*s.* per week for three visits, at which he offered prayers, accompanied by readings from "Christian Science" text-books and from the Bible. This gentleman declined at the inquest to admit that his "treatment" had been a failure, and was told by the foreman of the jury that he had juggled away the man's life. The coroner, however, pointed out that although if the deceased had been a child a verdict of manslaughter might have been returned against someone, as he was of full age he must be held to have been responsible for his own actions, and a verdict of "Death from septic poisoning" was returned.

The Case of an Unregistered Woman Practising as a Midwife at Leeds.

Three cases at Leeds, heard in the courts upon two consecutive days, recently called attention to the practice as a midwife of a woman named Johnson described as the wife of a miner. An inquest was held on Sept. 22nd on the ground that a child had been buried upon a medical certificate that it was still-born, whereas in fact it had been born alive and had died about three hours afterwards. Johnson had apparently attended the mother when she was confined, and had recommended the father to send for a medical practitioner as the child was "right bad." A medical student at the Leeds Infirmary proceeded to the house on the summons being received at the infirmary, but the child died a few minutes after his arrival in spite of his efforts to restore respiration. The resident obstetric officer at the infirmary, who was informed by the student that the child had given two gasps after his arrival, and that his attempt to induce artificial respiration had failed, after inspecting the body gave the certificate upon which the child was buried, and which stated that it was not born alive. This, he stated in evidence, was because it was prematurely born and could not have lived. In this case the jury returned a verdict of "Death from natural causes," and the coroner referred to the possibility of further inquiry being made with which the jury was not concerned. In that event, no doubt, an explanation of the giving of a certificate in the circumstances described or of

facts not explained at the inquest would be forthcoming. On the day following the inquest referred to a woman, the daughter of Mrs. Johnson, was summoned for registering the birth of her child as having taken place at an address where, in fact, it had not been born. The explanation given by the defendant was that the wrong address had been registered because she did not want to have the child vaccinated, but it was pointed out on behalf of the prosecution that she was delivered at the house of her mother, Mrs. Johnson, and that probably she gave the wrong address in order to avoid calling attention to the illegal practice of this person as a midwife. She was fined £1, to be paid in weekly instalments of 2*s.* 6*d.* In the third case referred to Mrs. Johnson was herself the defendant, and was convicted of habitually practising as a midwife for gain. It was stated that she had practised before the passing of the Midwives Act but had not been able to obtain registration under it, and that since April 1st of the present year, when all practice by unregistered women became illegal, she had continued to attend confinements. That she had done this on two occasions was proved, her defence being that she acted as a midwife without charge and was paid for nursing only. A fine of £5 was imposed, but the order was made that it was not to be enforced if the defendant desisted from infringing the law.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Oct. 6th, 1832.

WESTMINSTER HOSPITAL.

THE FIRST LIGATION OF THE CAROTID ARTERY EVER PERFORMED IN THIS COUNTRY.

JULY 14, 1832. Mr. Lynn attended with his usual punctuality, but there were no operations to perform, and he made a few conversational observations on the excision of tumours. "Forty years ago I was in the habit of frequently cutting out tumours, especially on the side of the face and neck, and the results were generally fortunate. I have often had some nice and difficult dissection on these occasions, and have had as many as four nerves at a time supported on the back of the fingers of my operating hand. My good fortune excited the emulation of my colleague Mr. Morell, who was a 'good creature,' but not the most brilliant of surgeons; and he said to me one day, 'Lynn, you are always cutting out tumours, why can't I do the same?' Quoth I, 'There is no reason in the world why you shouldn't.' 'Well then,' he said, 'I have an elderly woman who has diseased parotid gland, and I shall cut it out.' I replied, 'that I had never done that, and I did not think it an eligible case for a commencement especially.' However, he would have his own way, and he set about the operation very manfully, and did it very well; but I do not believe he actually cut out the entire gland, neither do I think it has ever been done completely by any one, before or since that time; and I told Sir Astley Cooper so, the other night at the College, when he was relating some of his cases. Well, to return to poor Morell, *he cut* out either the whole or part of the parotid gland, and put ligatures upon several vessels, but the ligatures slipped away, and hemorrhage occurred several times. As the poor woman was much exhausted by this loss of blood, Morell endeavoured to pucker up the wound, and involved it in a general ligature, but all his expedients proved vain, and the patient continued to lose blood almost every day for a fortnight. The fact is, he had cut off the arteries so near their main trunk, that he had left no room for a proper ligature. Foiled in all his attempts, Morell at last came to me, and asked what he should do. I answered, that the woman had lost so much blood, and was so much reduced in consequence, that it was doubtful if anything could save her.

"If the hemorrhage were not arrested, she must inevitably die in a day or two. Local ligatures were perfectly inapplicable. Cruickshank had lately been tying the carotids of dogs, and I saw no reason why the same operation should not be performed with impunity in the human subject, and if he liked, I would undertake to tie the primitive carotid. I accordingly cut down upon this artery just below its bifurcation by the side of the larynx, and found no difficulty in penetrating through the skin, platysma myoides, fascia, and sheath, and in ultimately tying the vessel with a single ligature. The hemorrhage instantly ceased, and no unusual effect was observed in the patient. She lived a fortnight after the operation, and died evidently of the debility induced by the hemorrhage and her previous sufferings. The case was fatal, but I felt satisfied the principle of the operation was established. This I believe to be the first instance of ligature of the carotid, and it certainly occurred long previous to any case that is recorded."

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Belfast.—The following summary gives the vital statistics for 1909: the birth-rate 28·2 per 1000, the death-rate 18·2 per 1000, the infantile mortality 139 per 1000 births, the zymotic death-rate (seven principal zymotic diseases) 1·3 per 1000, and the phthisis death-rate 2·3 per 1000. There is a reduction of 1·3 per 1000 in the general death-rate, the zymotic death-rate is the lowest on record, and the number of cases of infectious diseases notified was 2·5 per 1000, while in the preceding year it was 3·6, and the average for the 10 years 1899–1908 was 8·3 per 1000 of the population. There was a reduction in the number of cases notified of enteric fever, of simple continued fever, of membranous croup, erysipelas, and of diphtheria, and a slight increase in the cases of scarlet fever. The boundaries of registrars' districts as given are of no use; what is required is a map of Belfast showing them. 590 fewer births took place in Belfast in 1909 than in 1908. The birth-rate in Belfast has been on the decline for several years; the rate for the whole city was 28·2 per 1000 in 1909, as compared with 29·7 in 1908, whilst the average rate for the 10 years ended 1908 was 31·1, but the rate for 1909 shows the greatest reduction that has yet occurred in any given year as compared with the previous one, the rate being 1·5 less than in the preceding year. The number of deaths from all causes in 1909 was 7028, a decrease of 495 as compared with the previous year, when they numbered 7523. Of the total deaths, 2646 were due to diseases of the respiratory organs (including pneumonia and phthisis)—that is, 705 pneumonia, 811 phthisis, and 1130 diseases of the respiratory organs exclusive of phthisis and pneumonia. We think this huge group (1130) should be more differentiated. Malignant disease caused 298 deaths; there were 371 from tuberculous diseases (not phthisis), 244 from diarrhœa, and 213 from whooping-cough. With reference to puerperal fever, 23 cases were notified with 10 deaths, and of the 23 notified 13 were attended by "handy women," and in only four instances medical supervision was exercised over them at the outset, and six deaths occurred; while only two deaths occurred out of all the cases attended by qualified practitioners. Mr. H. W. Bailie says: "It is unfortunate that there are no means of putting an end to this unqualified practice, for it is quite reasonable to believe that in addition to the deaths which occur in connexion therewith many accidents must occur which lay the foundation of other ills which follow." The number of deaths from whooping-cough (213) were 76 in excess of the previous year, and the average for the preceding five years was 168 deaths per year. It is surely time such a death-causing malady was made notifiable. 811 deaths arose from pulmonary tuberculosis, that is, 1 in every 476 of the population died from this disease in Belfast in 1909, while in 1908 it was 1 in every 432. The rate from this malady was 2·1 per 1000, while it was 2·3 per 1000 in 1908. The average annual rate of mortality for the ten years 1899–1908 from pulmonary tuberculosis was 2·9 per 1000 of the population. During the first six years of this decade no decrease occurred, but during the four years 1905–1908 there was a decrease of 0·4 in 1905 and 0·2 in each of the following three years, and the year under consideration also shows a decrease of 0·2 per 1000 of the population. It is satisfactory to note a decrease in the death-rate from pulmonary tuberculosis, but the rate for 1909 (which is 2·1 per 1000) in Belfast is far too high when compared with similar sized English and Scotch towns. During the year 1909 1510

children died under one year, giving an infantile mortality of 139 per 1000, as compared with 147 in 1908. Among the 76 great towns of England and Wales there are only 10 with a higher infantile mortality than Belfast. Mr. Bailie attributes the greatest barrier to improvement to carelessness and neglect on the part of a certain class of mothers. It is satisfactory to find out that there has been a great increase in the number of bacteriological examinations during 1909. Reference has already been made in our columns to the part of the report dealing with alleged "sweating" in the linen industry. It is most satisfactory to find that the report shows in every respect a great improvement in admittedly bad conditions, and indicates that an attempt is now really being made to deal effectively with the public health of the city of Belfast.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 7733 births and 4338 deaths were registered during the week ending Oct. 1st. The annual rate of mortality in these towns, which had been equal to 11·7, 12·6, and 13·0 per 1000 in the three preceding weeks, further rose last week to 13·4. During the 13 weeks of last quarter the death-rate in these towns averaged 11·8, corresponding with the rate that prevailed in the 76 largest towns in the same period of last year. In London the death-rate during last quarter, calculated on the probably over-estimated population, did not exceed 11·0 per 1000. The lowest reported annual death-rates in these 77 towns last week were 5·3 in Hornsey, 5·5 in King's Norton, 5·8 in Handsworth, and 6·3 in Bournemouth; the rates in the other towns ranged upwards to 20·4 in Dewsbury, 20·5 in Wigan and in Middlesbrough, 20·7 in Rochdale, and 21·6 in Newport (Mon.). In London the reported death-rate last week did not exceed 13·0 per 1000. The 4338 deaths registered in the 77 towns last week showed a further increase of 104 upon the numbers returned in the three preceding weeks, and included 536 which were referred to the principal epidemic diseases, against numbers ranging from 720 to 590 in the five previous weeks; of these 536 deaths, 364 resulted from diarrhœa, 43 from whooping-cough, 37 from enteric fever, 35 from diphtheria, 32 from measles, and 25 from scarlet fever, but not one from small-pox. The mean annual rate of mortality from these diseases in the 77 towns last week was 1·6 per 1000, against rates ranging from 2·2 to 1·8 in the five preceding weeks. No death from any of these epidemic diseases was registered last week in Norwich, Halifax, York, or in seven other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·8 in St. Helens, 4·0 in Wigan, 4·4 in Bury, and 4·5 in Rhondda. The deaths attributed to diarrhœa in the 77 towns, which in the four preceding weeks had declined from 527 to 400, further fell last week to 364; in the several towns, however, they caused annual rates ranging upwards to 2·9 in Plymouth and in Middlesbrough, 3·5 in Bury, and 3·8 in Rhondda. The 43 fatal cases of whooping-cough showed a further decline, and were fewer than in any previous week of this year; the highest rate from this disease during last week was 1·6 in Rotherham. The deaths referred to enteric fever, however, which had been 12, 22, and 25 in the three previous weeks, further rose last week to 37, and considerably exceeded the number in any previous week of this year; they included 2 each in Wigan, Grimsby, and Dewsbury. The 35 fatal cases of diphtheria also showed a further increase upon recent weekly numbers, and included 12 in London and its suburban districts, 3 in Liverpool and Bootle, 3 in Manchester, and 2 in Newcastle-on-Tyne. The 32 deaths from measles were fewer than in any previous week of this year; and the 25 fatal cases of scarlet fever showed a decline of 2 from the number in the previous week. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased in the six preceding weeks from 1423 to 1560, had further risen to 1653 on Saturday last; 249 new cases of this disease were admitted to these hospitals during the week, against 183, 201, and 210 in the three preceding weeks. The 1215 deaths from all causes in London last week included 178 which were referred to pneumonia and other diseases of the respiratory system, showing an increase of 55 upon the number returned in the previous week, and exceeding by 33 the corrected average number in the corresponding week of the five years 1905–09. The causes of 35, or 0·8 per cent., of the deaths registered in the 77 towns during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, and in 50 other smaller towns; the 35 uncertified causes of death in the 77 towns included 6 in Liverpool, 5 in Gateshead, 4 in Birmingham, and 2 each in Norwich, Stoke-on-Trent, Sheffield, and Bootle.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 763 births and 497 deaths were registered during the week ending Oct. 1st. The annual rate of mortality in these towns, which had been equal to 13·0 and 13·6 per 1000 in the two preceding weeks, further rose to 13·7 in the week under notice. During the 13 weeks of last quarter the death-rate in these towns averaged 12·9 per 1000, and exceeded by 1·1 the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged from 8·4 and 12·9 in Aberdeen and Glasgow to 19 3 in Dundee and 19·6 in Perth. The 497 deaths from all causes in the eight towns last week showed a further increase of 3 upon the numbers in recent weeks, and included 83 which were referred to the principal epidemic diseases, against 78 and 72 in the two preceding weeks; of these 83 deaths, 51 resulted from diarrhœa, 14 from diphtheria, 8 from whooping-cough, 5 from measles, and 5 from scarlet fever, but not one either from "fever" or from small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 2·3 per 1000, the rate from the same diseases in the 77 English towns being only 1·6 per 1000. The deaths attributed to diarrhœa in the Scotch towns, which had been 45 and 47 in the two previous weeks, further rose to 51 last week, and included 21 in Glasgow, 11 in Dundee, and 5 each in Edinburgh, Paisley, and Leith. The fatal cases of diphtheria, which had been 10 in each of the two previous weeks, rose last week to 14, of which 5 occurred in Dundee, 4 in Glasgow, and 2 in Edinburgh and in Leith. Of the 8 deaths from whooping-cough, 3 were returned in Glasgow and in Aberdeen. The 5 fatal cases of measles included 3 in Edinburgh and 2 in Glasgow; and of the 5 from scarlet fever, 3 occurred in Glasgow and 2 in Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had been 42, 58, and 64 in the three preceding weeks, declined again to 61 in the week under notice, and were 5 below the number in the corresponding week of last year. The causes of 19, or 3·8 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 581 births and 393 deaths were registered during the week ending Oct. 1st. The mean annual rate of mortality in these towns, which had been equal to 15·1, 17·0, and 17·5 per 1000 in the three preceding weeks, further rose to 17·8 in the week under notice. During the 13 weeks of the current quarter the annual death-rate in these Irish towns averaged 16·3 per 1000; the mean rate during the same period did not exceed 11·8 in the 77 largest English towns and 12·9 in the eight principal Scotch towns. The annual death-rate during last week was equal to 20·2 in Dublin, 14·0 in Belfast, 21·2 in Cork, 21·6 in Londonderry, 15·0 in Limerick, and 13·6 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish towns was equal to 20·1 per 1000. The 393 deaths from all causes in the 22 town districts last week showed a further increase of 6 upon the numbers returned in recent weeks, and included 58 which were referred to the principal epidemic diseases, corresponding with the number in the previous week; these 58 deaths were equal to an annual rate of 2·6 per 1000, the rate from the same diseases last week being 1·6 in the 77 English towns, and 2·3 in the eight Scotch towns. The 58 deaths from these epidemic diseases in the Irish towns last week included 43 from

diarrhœa, 5 from diphtheria, 5 from whooping-cough, 3 from measles, and 1 each from scarlet fever and enteric fever, but not one from small-pox. The deaths attributed to diarrhœa, which had been 48 and 45 in the two previous weeks, further declined to 43 last week, and included 27 in Dublin, 7 in Belfast, 6 in Cork, and but 3 in the other 18 towns. The 5 fatal cases of diphtheria included 3 in Dundalk; and of the five deaths from whooping-cough, 3 occurred in Belfast and 2 in Dublin. The death referred to enteric fever was returned in Belfast and the fatal case of scarlet fever in Dundalk. The deaths in the 22 towns last week included 53 which were referred to pneumonia and other diseases of the respiratory system, against 47 and 54 in the two preceding weeks. The causes of 13, or 3·3 per cent., of the deaths registered last week in the Irish towns were not certified; in the 77 English towns the proportion of uncertified deaths last week did not exceed 0·8 per cent., while in the Scotch towns it was equal to 3·8 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: G. Welch to the *President*, additional, for special service at the Admiralty; and W. W. Pryn to Haslar Hospital, for instruction of surgeons on entry.

ROYAL ARMY MEDICAL CORPS.

The King has approved the appointment of Surgeon-General J. G. MacNeece to be Principal Medical Officer of the Eight (Lucknow) Division. Lieutenant-Colonel (local Colonel) H. B. Mathias, D.S O., principal medical officer of the Egyptian army, has arrived home on leave from Khartoum. Lieutenant-Colonel J. Meek, commanding the Station Hospital at Quetta, has been appointed to officiate as Principal Medical Officer of the Fourth (Quetta) Division. Lieutenant-Colonel J. R. Forrest has been reposted to the Irish Command on the expiration of his leave on medical certificate. Lieutenant-Colonel J. J. Russell, at present stationed at Limerick, has been appointed Staff Officer to the Principal Medical Officer of the Southern Command, England, with effect from Oct. 13th. Lieutenant-Colonel G. Cree, on expiration of his tour of service in India, has been detailed as Senior Medical Officer of the transport *Rewa*. Approval has been sanctioned for an exchange on the foreign service roster between Major G. T. Rawnsley and Major G. B. Carter serving at Dublin. Major G. B. Carter has been directed to proceed to India in March next. Major F. R. Bushwell embarked for a tour of service in India on the transport *Dongola* from Southampton on Sept. 21st. Captain L. Bousfield, on return home from Khartoum, has been posted to London District, being removed from the seconded list. Captain E. V. Aylen has been appointed a Specialist in Dermatology and Venereal Diseases to the First (Peshawar) Division. Captain A. E. Hamerton, D.S.O., has returned home from Uganda, where he was acting as a member of the Sleeping Sickness Commission. Captain R. C. Hallowes has embarked in the *Soudan* from Alexandria for home. The War Office has approved of an exchange on the foreign service roster between Captain R. L. Popham and Captain J. E. H. Gatt, serving at Cork and Cosham respectively. Captain S. M. Adye-Curran, serving at Queenstown, has been placed under orders to embark for India in the Northern Command about Nov. 4th next. Captain R. J. Cahill, Captain E. H. J. Luxmoore, and Captain K. A. C. Doig have been detailed for medical duty with troops on board the transport *Rewa*. Captain A. Chopping has been appointed a Specialist in Radiography and Electrical Science to the First (Peshawar) Division. Lieutenant C. Stoney has been posted for duty at Ipswich in medical charge of effective troops.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions of officers of the Indian Medical Service:—To be Colonel (dated May 25th, 1910): Lieutenant-Colonel Francis Casement Reeves. Captains to be Majors (dated July 28th, 1910): John Cyril Holdich Leicester, Hubert Innes, William Southwick Willmore, Albert Elijah Walter, Leslie Thomason Rose Hutchinson, Alexander Mathers Fleming, Ellacott Leamon Ward, John Norman Walker, Vivian Heathcote Roberts, and Thomas Spinks Ross. Lieutenant to be Captain (dated Feb. 2nd, 1910): Sites Chunder Chuckerbutty.

The King has also approved of the following admissions to the Service:—To be Lieutenants (dated Jan. 29th, 1910): Framroze Jamsetjee Kolaporewalla, Edward Galwey Kennedy, Robert Forrester Douglas MacGregor, Arthur Lewin Sheppard, Paul Knighton Gilroy, Joseph Arthur Alexander Kernahan, Maurice Lionel Corrie Irvine, Ernest William O'Gorman Kirwan, John Valentine Macdonald, George Lawrance Duncan, Anath Nath Palit, Hubert Alan Hirst Robson, Kalyan Kumar Mukerji, and Cecil George Howlett.

Captain Arthur Anderson McNeight, Royal Army Medical Corps, has been admitted to the Indian Medical Service by exchange with Captain R. K. White (dated July 11th, 1910).

Lieutenant-Colonel A. Street has received an extension of his leave home from India for a further six months. Lieutenant-Colonel J. R. Adie has been appointed by the Government of India for special duty to conduct an inquiry in regard to malarial fevers in the Punjab. Lieutenant-Colonel Cleveland, secretary to the principal medical officer, His Majesty's Forces in India, has been granted leave to proceed home. Major A. Leventon has been appointed to officiate as Civil Surgeon at Dacca, Eastern Bengal. Major G. Hutcheson, civil surgeon of Aligarh, has been deputed to the Central Research Institute at Kasauli for duty in the Government laboratories. Major G. Lamb (Bombay) has received an extension of his leave. Major T. H. Symons and Major J. W. Grant (Bombay) have embarked for India. Major H. Innes has been appointed Civil Surgeon at Mymensingh, Eastern Bengal. Major T. W. Irvine, second-class agency surgeon, Bombay Presidency, has been granted six months' privilege leave combined with furlough home from India. Captain T. McVean has been appointed to officiate as Agency Surgeon, Second Class, at Muscat, vice Captain J. Crossle, granted 15 months' leave. Captain H. Ross, officiating civil surgeon at Etawah, has been placed on special duty in connexion with the establishment of the Medical College at Lucknow. Captain J. B. D. Hunter, who has been officiating as medical officer in charge of the British Consulate at Seistan, has been appointed His Majesty's Vice-Consul. Captain M. R. C. MacWatters has been appointed to officiate as Medical Officer in charge of the 38th Regiment of Dogras. Captain W. L. Harnett has been appointed to the charge of the Brigade Bacteriological Laboratory at Jubbulpore and to the officiating medical charge of the 22nd Punjabis. Captain E. J. C. McDonald, district plague medical officer, has been granted three months' privilege leave. Captain W. H. Hamilton has been appointed a Specialist in Ophthalmology to the Second (Rawal Pindi) Division. Captain J. Fry has been temporarily appointed to the Sanitary Department in Bengal. Captain T. Wallis has been selected to officiate as Deputy Assay Master, Bombay. Lieutenant R. E. Wright has been appointed a Specialist in Otology, Larnygology, and Rhinology to the Burma Division. Lieutenant J. Sewell has been selected to officiate as Surgeon Naturalist to the Marine Survey of India.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Attached to Units other than Medical Units.—Lieutenant Samuel Maclean to be Captain (dated May 19th, 1910).

HASLAR HOSPITAL.

The course of instruction for surgeons at Haslar Hospital will close to-day (Oct. 7th), when Admiral Sir John Durnford, K.C.B., D.S.O., will distribute the prizes.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—A special course of lectures and demonstrations on the nervous system will be given at this hospital during the months of November and December at 5 o'clock in the afternoon. On Tuesdays Dr. Gordon M. Holmes will lecture on clinical anatomy; on Wednesdays Mr. Donald J. Armour will lecture on surgery; and on Thursdays Dr. James Collier will discuss the clinical examination of cases. The fee for the whole course is 5 guineas, and for one of the three parts of the course 2 guineas. Further particulars can be obtained from the Dean, at the hospital, Queen-square, Bloomsbury, Londor, W.C.

Correspondence.

"Audi alteram partem."

THE REGISTRATION OF THE MEDICAL STUDENT AND THE REGULATIONS OF THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—I hope you will allow me to answer as briefly as possible the letter of Mr. Bevan printed in your issue on Oct. 1st. If I make any incorrect statement the Registrar of the General Medical Council will doubtless set me right.

The London University recognises as the first year of the five years' medical course a year spent (after matriculation) at St. Paul's School or similar schools in the study of chemistry, physics, and biology. A student who has thus spent a year can proceed to the M.B., B.S. degrees after four years at a medical school. The General Medical Council does not "register as a medical student" such a person until he actually enters the medical school. But this makes no difference whatever to him. The General Medical Council has no power to enforce the interval between "registration as a student" and "registration as a practitioner," and it has no power to refuse to register as a practitioner forthwith an applicant who has the degrees referred to or the qualifications of the Royal Colleges.

Mr. Bevan is quite right in thinking that many parents are misled by the form of the statement issued by the General Medical Council. The intention of the Council was doubtless right. It meant to prevent the premature specialisation in medical work. But the effect has been precisely the opposite of that intended. Instead of inducing the student to prolong his "general education," it tempts him (by the ungrounded fear of losing a year) to go to a medical school at the earliest possible moment.

I have no desire to enter into the question whether it is or is not desirable in the case of students who matriculate (or otherwise qualify) early that they should spend the first year of their medical curriculum at school. I do not even ask that the regulations issued by the General Medical Council should point out the possibility of this, since the possibility depends not on the Council but on the licensing bodies. All I suggest is that the regulations issued by a public body should not be actually misleading. A parent would require to have a legal knowledge of the respective powers of the Council and of the licensing bodies if he is not to be misled by this statement in the Council's regulations:—"The commencement of the course of professional study recognised by any of the Licensing Bodies shall not be reckoned as dating earlier than fifteen days before the date of registration."

I am, Sir, yours faithfully,

A. E. HILLARD, D.D.,
High Master of St. Paul's School.

West Kensington, W., Oct. 3rd, 1910.

To the Editor of THE LANCET.

SIR,—Perhaps my personal experiences regarding the regulations laid down by the General Medical Council as to registration of a student may be of use to your correspondent, Mr. R. Bevan. I was educated at Epsom College, a school which, I believe, was founded in the first place for those going in for the medical profession. From there I passed first the London Matric. and then the Pre. Sci. (M.B.), first part (chemistry, physics, and zoology). After this I was registered as a student and entered a London hospital.

At the end of four years I wanted to have a shot at the final Conjoint. I was refused admission on the ground that I could not be signed up for a five years' course at a recognised medical school. But I was told my year's work at Epsom would count as half a year towards the five! I tried to go in for the L.S.A. final and was refused on the same grounds. As a last resource I applied to the London University, who admitted me without demur. After the examination I inquired of the registrar of the Medical Council whether I could be now registered as a practitioner, although I had been registered as a student for four years only. The answer was that I certainly might, since the Council could not refuse to register a man who had duly passed his final. I think that these experiences will show that somehow the regulations are, to say the least of it, inconsistent, and I hope that they may help some other man in the same boat.

Finally, may I put in a plea that the General Medical Council at least extend the privileges of a recognised medical school to Epsom College? I am confident that the first year's training there is as good as, if not better than, that at any recognised medical school. Should my experiences be of any practical use to Mr. Bevan I shall be glad to communicate with him direct.

I am, Sir, yours faithfully,

HUGH L. BURTON, M.B.

13, Truro-road, St. Austell, Oct. 2nd, 1910.

THE COST OF SANITATION IN THE TROPICS.

To the Editor of THE LANCET.

SIR,—In the report on the measures taken against malaria in the Lahore Cantonment, which I have just received from the authors, Messrs. Nathan, Thornhill, and Rogers, the conclusion is reached that anti-malarial operations, such as have been carried out so successfully in other countries, cannot be readily adopted in India, chiefly on account of the great cost. Panama is cited in illustration. The statement is made on the authority of Colonel Macpherson: "That the total cost of sanitary and medical measures amounted to two millions of dollars per annum, or about a tenth of the total annual expenditure on the Canal works." Colonel Gorgas has recently denied this statement. His paper is published in the Gulf States *Journal of Medicine and Surgery* (July, 1910), and as it is, perhaps, not very accessible, the following quotations will be of interest. "The ordinary man in speaking of the Sanitary Department has in mind a department such as the Health Department of New York. Besides performing such functions as the Health Department of New York performs, the Sanitary Department on the Isthmus cares for all the sick, both in the hospitals and at dispensaries, administers the national quarantine, does the street cleaning and garbage collecting, fills in drains and reclaims waste lands, pays the salaries of some fifteen ministers of the Gospel, cares for all the cemeteries, does a general undertaking and embalming business for some 80,000 people, and besides all this, pays directly to the Engineering Department about $200,000 per year. Up to July 1st, 1909, Congress has appropriated $7,927,840 for the Department of Sanitation on the Isthmus. Of this $7,927,840 appropriated for the Sanitary Department, Congress has taken away and given to the construction department $938,827. This leaves the total appropriation for the Sanitary Department $6,989,013. Considering the 62 months covered by the period from May 4th, 1904, to July 1st, 1909, this gives us an appropriation at the rate of $112,726 per month. This would give us a yearly appropriation for the first years since the Sanitary Department has been organised of $1,352,712."

"Taking the fiscal year 1908 and 1909, we find that one-fourth of our expenditures were for sanitation. Apply the same rates to the average yearly appropriation, $1,352,712 divided by four gives us $338,178 as the annual appropriation for sanitation. Considering our average population for the past five years as one hundred thousand, we have the *per capita* appropriation for sanitation during the same period as three dollars and thirty-eight cents *per capita* per year, or 28c. per month."

"When we consider the great changes for the better that have been accomplished by the expenditure, I think that we will all agree that it has been very economically accomplished. Such expenditure is certainly well within the means of any tropical community."

I am, Sir, yours faithfully,

University of Oxford, Oct. 3rd, 1910. WM. OSLER.

THE MEDICAL REGISTER.

To the Editor of THE LANCET.

SIR,—Will you once more kindly draw the attention of members of the profession to the importance of keeping their addresses correct in the Medical Register? Circulars are not issued every year, and practitioners should themselves notify changes; failure to do this may result in the removal of the name because it is impossible to communicate with the practitioner, though every possible effort is made to avoid such a course. No person whose name is not on the Register

can give a valid certificate, and the signatures upon certificates of death are now compared with the Register by local registrars. Any practitioner who has any doubt as to the correctness of his address should at once communicate with this office. An acknowledgment will be sent of the receipt of all communications.

I am, Sir, yours faithfully,
H. E. ALLEN, Registrar.

Medical Council Office, 299, Oxford-street, London, W., Sept. 28th, 1910.

THE TREATMENT OF THE MORPHIA HABIT.

To the Editor of THE LANCET.

SIR,—In your Paris correspondence of Sept. 3rd mention is made of a preparation of opium "discovered" by M. Sahli of Berne and recommended by Dr. Moret-Lavallée in the treatment of the morphia habit. This preparation, pantopon, represents the totality of the alkaloids of opium, and its substitution for morphia is manifestly an important step in the transition towards final renunciation. I have in a recent contribution to the question (Morphinisme et Morphinomanie) pointed out the value of this composition which I have been using for nearly a year, and I have shown also that the weaning (for timorous subjects) can be rendered even still easier by the successive substitution of two other opium preparations of gradually decreasing strength. These are: (1) demorphinised pantopon—i.e., the totality of the opium alkaloids minus morphia; (2) a preparation in which all the alkaloids are eliminated except those constituting what is known as the meco-narceic group.

The demorphinised pantopon was realised for me four or five months ago by MM. Hoffmann-La Roche, but I have used the solution of meco-narceic alkaloids ever since its introduction by Duquesnel, and have frequently called attention to it both in your own columns and in other publications. I am, Sir, yours faithfully,

Le Vesinet, France, Sept. 29th, 1910. OSCAR JENNINGS.

A CASE OF CONGENITAL UMBILICAL HERNIA CONTAINING THE LIVER AND MOST OF THE SMALL INTESTINE.

To the Editor of THE LANCET.

SIR,—The following case may be of sufficient interest to warrant its publication. The patient, a primipara, aged 22 years, was seen by me on July 8th. She stated that she was 7½ months pregnant. The membranes had just ruptured, and a very large quantity of liquor amnii had escaped. About an hour afterwards she was delivered naturally of a male child with an enormous umbilical hernia, which contained all the liver and most of the small intestines. There was also well-marked "talipes equinovarus" present. The child survived its birth for 15 minutes.

It is curious to note that if this condition was in any way caused by the increased intra-uterine pressure, i.e., the hydramnios, which was undoubtedly present, the child should have been born alive.

I am, Sir, yours faithfully,
B. G. S. BELAS,
Senior House Surgeon, West Kent Hospital,

Maidstone, Sept. 28th, 1910. Maidstone.

THE Lord Mayor and Sheriffs attended the opening of the winter session of the Middlesex Hospital Medical School on Oct. 3rd, when Viscount Kitchener of Khartoum distributed the prizes to successful students. Among the prize-winners were the following:—First entrance scholarship, D. C. Ogilvie; second entrance scholarship, R. H. Fleming; third entrance scholarship, L. G. Phillips; Freer Lucas entrance scholarship (Epsom), H. Wearne; University scholarship, G. E. Beaumont; New Zealand students' scholarship, T. W. J. Johnson; first Broderip scholarship, B. S. Simmonds; second Broderip scholarship, G. O. Teichmann; John Murray gold medal and scholarship, B. S. Simmonds; Freeman scholarship, E. A. Runting; Hetley clinical prize, A. O. English; Lyell gold medal and scholarship (*prox. acct.*), A. O. English and G. O. Teichmann; Leopold Hudson prize, E. L. P. Gould; second year's exhibition, A. O. Gray.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

A New Sanatorium for Consumptives.

EXPERIENCE of the treatment of early cases of consumption at the municipal sanatorium at Salterley Grange soon impressed the health committee with the necessity for making some provision for cases of a more advanced nature. This has now been done. The hospital in Yardley-road, originally intended, but never used, for small-pox cases, has, with a few necessary alterations, been converted into an open-air sanatorium. Two large buildings have been taken over, one to accommodate 26 males, the other 24 females. Each ward is divided into four divisions, three for sleeping and one to be used as a dining and recreation room. A long verandah has been attached to one side of each ward, and two shelters have been erected in the grounds. The total cost of the alterations and additional furniture is estimated at £1200 and the cost of maintenance at £2500 per annum, which works out at about £1 per week per patient. The institution will be under the direction of Dr. W. H. Wynn, assistant physician to the General Hospital, who has been appointed visiting physician, and Dr. Godfrey Dixon of the Vale of Clwyd Sanatorium, who has been appointed resident medical officer. Admission to the institution is open to any *bonâ-fide* Birmingham resident who is suffering from tuberculosis of the lung in a rather more advanced stage than would entitle him to admission to Salterley Grange Sanatorium. The treatment will be for a definite period of six weeks, during which time every endeavour will be made to improve the general condition of the patient by open-air and other treatment, while at the same time instruction will be given in methods of preventing the spread of infection during coughing and spitting. Admission will only be by certificate from a medical practitioner to the effect that the patient is suffering from tuberculosis of the lungs, and preference will be given to those cases in which the infection is likely to be of prolonged duration. It is hoped that the institution will prolong the wage-earning capacity of a large number of consumptives and be the means of preventing infection from spreading when they return home, and also of demonstrating to numerous Birmingham residents the necessity of fresh air.

Children's Hospital.

The King Edward Memorial Fund, promoted by the *Birmingham Daily Mail* mainly for the rebuilding of the Children's Hospital, has met with considerable success. £25,000 have been received or promised up to date. The hospital committee has several thousand pounds in hand, and this, together with a substantial legacy, which will shortly fall due, and the balance of the Memorial Fund after paying for a statue, brings the total available for the hospital to about £30,000. The committee therefore feels itself justified in commencing building operations in the near future. The hospital, as now designed by Mr. F. Martin, will have 130 beds, more than double the number available in the present building. The hospital portion proper will consist of four accident wards, containing 16 beds each, in two-storey buildings, and five general wards with 14 beds, all capable of being worked on the open-air system. The roofs of these blocks will be flat and capable of taking a large number of additional beds, while at a slight extra expense they can be converted into full-ward units. Provision has been made for those patients who may require enclosed rooms, and the general wards, while open to the air under normal conditions, will be fitted with glazed windows which can be placed into position in stormy weather, so that at very short notice they can be converted into wards of the ordinary enclosed type. There will be two operating theatres and rooms for X ray examinations, and a septic and infectious block with 12 beds. It is expected that the total cost will be well within £50,000.

The Daily Bath in Schools.

At two of the Birmingham schools situated in poor districts—Floodgate-street and Gem-street—there has been for some time past provision for shower-baths. At Floodgate-street School there are 10 shower-baths and from 350 to 400 children receive a bath once a week. At Gem-street there are four shower-baths and a small plunge-bath. They are used by the children attending the deaf centre and the mixed school, and on the average 150 children are bathed every

week. At each school is an apparatus for stoving the clothes of verminous children. The bathing is done in school hours and forms part of the school curriculum, and so greatly do the children enjoy it that the greatest punishment a teacher could inflict would be prohibiting a child from having a bath. Abundant evidence is forthcoming of the increased mental and physical activity, increased power of attention, and lessened tendency to disease that have been experienced.

Oct. 4th.

WALES.

(FROM OUR OWN CORRESPONDENTS.)

Welsh National Memorial to King Edward.

WHILE suggestions were being made in several towns of North and South Wales with regard to local memorials to the late King Edward, the Lord Mayor of Cardiff, in June last, called a conference at Cardiff of representatives from all parts of the Principality to consider the desirability of promoting a memorial of a national character. The conference decided that such a memorial should be established, and that the precise form it should take should be left to a future meeting, although it was generally understood that it must appeal to the whole of Wales, and must deal with the welfare of the people. The Lord Mayor of Cardiff invited suggestions to be sent to him, but from the first it seemed apparent that the memorial would take the form of the provision of institutional treatment for consumptive persons living in Wales. A far more comprehensive scheme than the mere erection and maintenance of sanatoriums has now, however, been decided upon, and at the resumed conference, which was held at Shrewsbury on Sept. 30th, it was unanimously resolved to approve the principle of a national campaign against tuberculosis with a view of completely stamping out the disease as the most appropriate form of national memorial to the late King Edward VII. Mr. David Davies, M.P., whose grandfather was one of the principal founders of the town of Barry, has taken a prominent part in the proposed scheme and has promised to contribute £25,000 towards its cost. It is intended to raise a fund of £300,000, one half of which has already been promised. Any and every recognised measure for lessening the ravages of tuberculosis are to be included in the scheme. Besides the erection and endowment of sanatoriums there are to be tuberculosis dispensaries, and arrangements are to be made for providing health visitors and for educating the people by means of lectures, &c., while the condition of the milk-supplies is to be inquired into. At present the only two institutions in Wales for the treatment of consumptives are the West Wales Sanatorium for the counties of Cardigan, Carmarthen, and Pembroke, and a small institution in Anglesey. In the five years 1904–08 the death-rate at all ages from phthisis in England and Wales was 1·2 per 1000 per annum. In the English and Welsh counties the highest rates were in Cardigan (2·3 per 1000), Merioneth (1·6 per 1000), Carmarthenshire (1·6 per 1000), Carnarvonshire (1·6 per 1000), and Pembrokeshire (1·4 per 1000). There appears, therefore, to be ample need for such a campaign against the disease as that which is contemplated.

Swansea Garden City.

There is now being held in Swansea under the auspices of the National Housing and Town Planning Council a cottage exhibition the objects of which are to provide examples of modern suburb planning under existing by-laws; to stimulate the building of well-arranged and comfortable houses capable of being let at rents within the means of workmen, and to provide architects and builders who desire to improve upon existing methods of planning and building workmen's cottages with an opportunity of showing the value of their improvements in a definite and practical manner. A portion of an estate, 50 acres in extent, and which belongs to the Swansea corporation, has been given up for the purposes of the exhibition. In the first instance prizes were offered for the best site plan and no less than 80 architects competed. The site was then laid out by the corporation in accordance with the plan adjudged the best. There were subsequently erected 29 cottages at a cost varying from £202 to £350. There are not more than four houses in any one block and the maximum number of houses per acre is 20. The ground rent charged by the corporation is equal to about £18 per acre. The site is not an economical one to build upon, for it is situated on the side of a hill which overlooks Swansea Bay. The need for houses in Swansea at the present time is very great, and it is hoped that the venture of the National Housing Council may stimulate the local builders to supply that need either on the corporation estate or elsewhere.

Oct. 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The British Hospitals' Association.

THE first annual conference of the British Hospitals' Association was held at Glasgow University last week. In the absence of Mr. H. Cosmo Bonsor, the President of the association, the chair was taken by Mr. J. D. Hedderwick, chairman of directors of the Royal Infirmary, Glasgow. In the afternoon of the first day the members were entertained to luncheon at the City Chambers, Lord Provost McInnes Shaw presiding. During the days of meeting of the conference discussion took place on matters bearing on hospital management and development. A paper was read by Mr. Charles Stewart Loch, secretary to the council of the London Charity Organisation Society, on the "Social Policy of Voluntary Hospitals." He suggested that every patient in a hospital should pay according to his ability, and that medical men who took part in the work of the hospitals should be remunerated. This general policy, he argued, would lead to a better remuneration of medical men, to a better division of labour among institutions for the sick, and to a very serviceable association in charity. "The Abuse of the Hospital and its Cure" was treated by Mr. A. Scott Finnie, treasurer, Aberdeen Royal Infirmary, who pointed out that the growth of the numbers of those receiving free hospital treatment left little room for doubt that very many were improperly availing themselves of such treatment and of the gratuitous services of the medical and surgical staffs. A first step in real reform would be a conference between representatives of all the interests involved. Subscribers would express their views as to the bestowal of their benevolence, hospital governors would tell of the difficulties experienced, and workmen's representatives would give valuable aid in determining appropriate standards of inability to pay, keeping in mind other provisions for times of sickness. In the discussion it was pointed out that as long as there was no provision for the poorer middle-class sick it was futile to talk about abuse of hospitals. It was generally agreed that there was a need for paying hospitals. As things at present stood, special treatment could be obtained by the rich and by the poor which was beyond the reach of the middle class, if the question of hospital abuse was looked upon in too narrow a spirit. A paper was also read by Mrs. Sidney Webb on the Coming of a Unified County Medical Service and how it will affect the Voluntary Hospital. According to her it would make little difference. Let the municipality do what it would, there would always be people anxious to contribute to hospitals, and there would be always even an incessant growth of new and additional hospitals. The final paper was read by Dr. Nathan Raw on the Institutional Treatment of Tuberculosis.

Caledonian Medical Association.

The Caledonian Medical Association held its annual meeting at Fort William. Dr. A. Cameron Miller (Fort William) was elected President for the ensuing year in succession to Dr. David Blair (Lancaster). A paper entitled "The Physician in Fiction" was read by Dr. Miller, and other contributions, including one of special local interest by Professor Mackendrick on "Reminiscences of Lochaber," were submitted. In the evening the annual dinner was held in the Alexandra Hotel. The toast of "The Society" was proposed by Provost Mackenzie. Lord Morton invited the members to a cruise in his yacht the following day.

Notification of Births in Aberdeen.

In Aberdeen the working of the Notification of Births Act has been exceptionally successful, largely owing to the system of Dr. Matthew Hay. In explaining the plan of procedure adopted Dr. Hay said: "When the Act came into force I sent a summary of its provisions to all the medical men and nurses in the town, pointing out what they were called on to do. For a time there were omissions, and

there are so still; but they have been reduced to almost vanishing point." Dr. Hay gets from each registrar a return of the births registered with him each week, and these he carefully compares with the notifications he receives. "Thirty-six hours are allowed under the Act for notification being made, and we allow them a week. When, however, we come across a late notification we send a note to the parent drawing his attention to the penalty he has rendered himself liable for. In the same way in cases of failure to notify we send a punitive letter to the parent, who is of course the first person mentioned in the Act. The parent who receives such note generally comes here in fear and trembling to explain that he did not know such a duty was imposed upon him. I point out to him that parents are supposed to know the law. The result is that those people speak to their doctor about the trouble they have got into, and say he should have informed them what to do. A doctor naturally does not like to have differences with his patients, and accordingly he makes it a point in all further cases to inform the parent or the nurse of the necessity for notifying the medical officer of the birth and of the penalty to be inflicted for not doing so. In that manner the medical men are drilled and the efficient working of the Act secured. What medical men contend is that they receive no fee for notifying. I think they ought to be paid, but of course we have not the making of the law, but only the administration of it. For the whole month of September there have only been four late notifications, and all over the omissions only amount to about 5 per cent."

The New Sick Children's Hospital for Aberdeen: Her Majesty the Queen to become Patron.

A special committee of the directors of the Aberdeen Royal Hospital for Sick Children met on Sept. 29th to receive the report of a subcommittee as to the best means to be taken to provide new hospital buildings. It was announced that Her Majesty the Queen had graciously expressed her willingness to become patroness of the institution. It is hoped that this further mark of Royal favour, which will greatly gratify the public of Aberdeen, will be the means of spurring on the efforts to provide funds to erect new hospital buildings. The directors expect that they will be able to secure a suitable site within the city. It has been suggested that the new buildings would form a most appropriate memorial to His late Majesty King Edward, and might bear the title of "The King Edward Memorial Hospital."

Red Cross Society: Meeting in Aberdeen.

A meeting of this society was held on Sept. 30th in the Town and County Hall, Aberdeen, for the purpose of organising a county branch of the British Red Cross Society, and to hear Major Fleming, D.S.O., secretary of the Scottish branch, explain the objects and methods of the society. The office-bearers of the branch have been appointed already and are as follows:—President: The Countess of Aberdeen. Vice-presidents: Lady Cathcart, Mrs. George Coats, Mrs. Duff, the Countess of Erroll, Lady Leith, Mrs. Russell, and Lady Saltoun, with Mr. William Smith, advocate, as the honorary secretary and treasurer. Lady Aberdeen presided, and there was a large and representative attendance. Mr. Haldane sent a letter regretting his inability to be present and saying that the War Office and the General Staff attached great importance to this work as it helped their scheme for home defence and trained men and women in time of peace to do what would prove most valuable in time of war. He sent his best wishes for the movement in the county. Lady Aberdeen in her speech thanked those who had come to the meeting to give a good send-off to the Red Cross Society in Aberdeenshire. The work of the society did not seem to take hold of Britain until recently, when the late King Edward and Queen Alexandra issued an appeal to the people of the country to organise the society. In other countries the society had flourished. The Red Cross Society was not only organised to meet the needs of war, but it was intended to train the citizens to be prepared to meet all kinds of national emergencies. Major Fleming explained the working of the society, and Emeritus Professor Alexander moved the first resolution:—

That the Right Honourable Robert Farquharson of Finzean be appointed director for the county, and Dr. Cran (Banchory) assistant director.

The motion was unanimously agreed to, and Dr. Farquharson moved:—

That the Red Cross Society be organised in the county by forming three divisions—namely, (1) the Buchan and Formartine Division; (2) the Donside; (3) the Deeside, and that the following be appointed to act as Vice-Presidents: Countess of Aberdeen for Buchan and Formartine; Lady Sempill for Donside; and Mrs. Coleman of Lillyprome and Bielack for Deeside Division.

Lord Sempill seconded and the motion was adopted.

Sudden Death of a Broughty Ferry Doctor.

The death took place very suddenly on Sept. 24th of Dr. George Grant at his residence, Lomondbank, Broughty Ferry. Born at Tomintoul 49 years ago, he was a son of the late Mr. James Grant, LL.D., one of the most successful and best known of Scottish teachers. For the past few months the deceased had been in indifferent health, but the end came suddenly. Deceased was educated at his father's school in Keith, and then went to Aberdeen University, where he had a distinguished career. Shortly after graduation Dr. Grant went to East Lancashire, where he practised for over 20 years. There he interested himself in ambulance work and was, indeed, one of the originators of the movement in East Lancashire. He was also at one time an enthusiastic volunteer and held the rank of captain in one of the East Lancashire corps. He went to Broughty Ferry five or six years ago, and continued, but only to a limited extent, to practise his profession. He married a daughter of the late Mr. James Strachan, Brae, Keith, and sister of the late Professor Strachan of Manchester, the eminent Celtic scholar. He is survived by his widow and a daughter. Of a most unassuming and kindly disposition, Dr. Grant was held in high esteem, and the news of his death will be received with deep regret.

Oct. 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Report of the Local Government Board.

THE publication of the annual report of the Local Government Board for Ireland for the year ending March 31st last allows some particulars to be added to those published in THE LANCET of August 20th (p. 593). The number of cases of typhus fever was 182, as compared with 162 in the previous year; the increase is due to an outbreak of over 50 cases in the Belmullet district. An outbreak of typhoid fever occurred in Kilworth camp, and was traced to a typhoid carrier, a dairymaid on a farm which supplied the camp with milk. This girl had had typhoid fever in 1903, and though she remained in good health ever since, several persons who had been associated with her had developed typhoid fever. When her condition as a typhoid carrier was established by the discovery of typhoid bacilli in her urine, the girl was brought to a Dublin hospital that her case might be thoroughly investigated. A full report is supplied by Professor E. J. McWeeney. The urine contained large numbers of typhoid bacilli, but on no occasion were any found in her fæces. Treatment by drugs and by vaccines was useless, and after six months there was still bacilluria.

Infant Mortality and Pasteurised Milk.

At the last meeting of the South Dublin Guardians the master submitted a return of the deaths in the nursery and crèche for the years 1906, 1907, 1908, 1909, and 1910. Mr. Crimmins said that in 1907 a committee was appointed to consider the death-rate in the nursery and crèche. It recommended that an experiment should be tried of feeding the children on ordinary new milk warmed to the natural heat of the cow. That recommendation was adopted, and the result was seen in 1908 and 1909, when the deaths fell to 95 from 113. Then, in 1909, on the recommendation of Dr. Dunn, pasteurised milk was substituted as the food for the children, and the death-rate jumped up to 129. This report has naturally given rise to considerable alarm. The honorary secretary of the Pasteurised Milk Depôt of the Women's National Health Association of Ireland has written to the papers, pointing out that the South Dublin Union experience differs from experience elsewhere. The report is, of course, unconvincing, in that no information is given concerning overcrowding and the sanitary condition of the nursery generally.

Freedom of the City of Dublin Conferred on Sir Charles Cameron.

Last week the corporation of Dublin unanimously elected Sir Charles Cameron, medical superintendent officer of health, an honorary freeman of the City of Dublin. Sir Charles has been in the service of the corporation for nearly half a century, and for 30 years has occupied his present position. Although the health of Dublin is still in a highly unsatisfactory condition, there has, of course, been great improvement in 30 years. The death-rate has come down from 37 per 1000 to 22. The compliment is a pleasant expression of the cordial personal feelings which Sir Charles Cameron has always been so fortunate as to evoke in those with whom he has been associated.

Appointment of City Bacteriologist for Dublin.

After over a year's deliberation the corporation of Dublin has elected a bacteriologist for the city in the person of Dr. M. Russell. The remuneration is to be in the form of fees for certain specific investigations. In the first instance, the corporation invited candidates for the post to state the fees for which they were willing to undertake certain investigations. The resulting tenders showed such absurd differences in the value at which the candidates estimated their professional work that the corporation officials had themselves ultimately to draw up a definite scale. The fees granted, while not erring towards generosity, cannot be regarded as inadequate.

Fatal Accident to a Medical Man.

A fatal cycling accident occurred last Saturday evening in the northern part of County Dublin to Mr. P. J. Smyth, a medical man practising in Stamullen. While riding home shortly after dark he apparently missed the road and ran into a wall, dislocating his neck. He was found dead a few minutes after the accident. Mr. Smyth practised in the neighbourhood for many years.

King Edward Memorial in Belfast.

The first meeting of the general committee, which was appointed at a public meeting on Sept. 13th, took place on Sept. 29th, and an executive committee was selected of 29 members, of which the Lord Mayor is chairman, and five are to form a quorum. On this representative body care has been taken that every interest is represented among the subscribers. Sir John Byers and Dr. R. J. Johnstone, secretary of the medical staff of the Royal Victoria Hospital, were chosen as the medical members. The amount subscribed is now £12,500.

New Cottage Hospital at Bangor.

The new Cottage Hospital in Bangor, the health resort at the east side of Belfast Lough, was opened on Saturday, Oct. 1st, in the presence of a very large and representative assemblage. The building, which has been simply treated in the Early Georgian style, is beautifully situated in spacious grounds of its own. It has been designed for about 24 patients and contains suitable accommodation for them and for the administrative staff, and an excellent operating theatre. The cost of building and equipment—about £4000—has been practically covered by contributions, only a sum of between £300 and £400 being now required to open the place free of debt. In the course of the inaugural proceedings Professor J. A. Lindsay said there was one problem—hospital abuse—which required solution, and in order that this solution should be final and satisfactory three things would have to be taken into consideration. The first was that the needs of the sick and injured who could not pay for their own treatment should be adequately met; the second was that the money of the charitable public should not be spent upon those who were not proper objects of charity; and the third was that the just and reasonable rights of medical practitioners should not be unduly interfered with. All the medical men in Bangor can attend cases in this institution, and while the life-governors and the subscribers may nominate the poor for free treatment, all who can contribute are expected to do so. Mr. John Gorman gave the meeting many interesting details about the new hospital.

Sewage Disposal and Flooding in Belfast.

Two important and matured schemes were presented to the Belfast City Council at its meeting on Oct. 3rd, and passed, in reference to sewage disposal and flooding in Belfast. They came from the improvement and public health committees. The one scheme is for the completion of the sewage sedimentation plant, and the other for the tapping at high levels of the mountain streams and the carrying away from them of flood-water by culverts as a practical remedy for flooding in the low levels of the city, and especially at the part of the city known as Greencastle. The completion of the sewage sedimentation plant will cost £61,000, in addition to the £44,000 already expended, while the diversion of the flood water at high level by culverts will entail an expenditure of £90,000.

Oct. 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Death of Professor Raymond.

FRENCH medical science has sustained a serious loss by the death of Professor Raymond, who has passed away at the age of 66 years. He was a professor at the Faculty of Medicine, a member of the Academy of Medicine since 1899, and a Commander of the Legion of Honour. He was a pupil of Vulpian and Charcot, and was marked out by the latter to be his successor in his hospital practice and in his chair at the Salpêtrière. Professor Raymond received these appointments in 1894 and became one of the greatest authorities on the subject of nervous diseases. Originally intended for a veterinary career, he joined the school at Alfort when 17 years of age, ultimately obtaining the position of *chef de service* in the department of anatomy and pathology, but as he now found himself attracted to the medical profession he entered the School of Medicine when 23 years of age. In the competition admitting to the position of hospital *interne* he took the second place, being then 28 years of age, and at the end of his period of office he received the gold medal. He became *chef de clinique* at 33 years, hospital physician at 34 years, and *agrégé* at the Faculty in 1880. His clinical lectures on nervous diseases at the Salpêtrière were very well attended. In 1908 the University of Oxford conferred upon him the honorary D.Sc. degree.

Probationer Nurses.

An examination is now being held for the admission of 100 probationers to the nursing school of the Assistance Publique. Candidates must be women of good constitution from 19 to 26 years of age; those who have not the opportunity of staying with a family in Paris receive free board and lodging in the school during the period of the examination. In addition to emoluments in kind, such as sleeping accommodation, food, and clothes, they are paid 10 francs per month for the first year and 20 francs per month for the second year; they must also agree to serve in the institutions of the Assistance Publique for three years, with the alternative that in case of failure they must repay the cost of their maintenance at the rate of 1095 francs per annum. On leaving the school the pupils who pass the final examinations are provided with situations as second-class nurses in the institutions of the Assistance Publique, receiving emoluments in kind as already mentioned and wages of 700 francs per annum.

International Medical Association for the Prevention of War.

At the general meeting of the International Medical Association for the Prevention of War it was decided that the first congress shall be held in Paris in June, 1911. The meeting passed a vote of thanks to the press of all countries which has done so much to spread abroad a knowledge of the ideas and views of the association.

Action for Damages against Medical Men.

The civil tribunal of Toulouse recently decided an unusual case originating in a dispute between the Syndicate of Medical Men of Toulouse and the Federation of Mutual Aid Societies. The syndicate had obtained 160 withdrawals from the service of the societies and had given notice to terminate contracts made with some of the more important among them, but in one of the societies three medical men took the places of practitioners who had withdrawn. The syndicate in return put them on its "index," the effect of which was that they were regarded as not in practice; all professional coöperation with them was forbidden, and every member of

the syndicate who might enter into professional relations with them made himself liable to a fine varying from 20 to 100 francs, which might be doubled in the event of a second offence. One of these three medical men thereupon brought an action before the tribunal, claiming 100,000 francs damages against the president and secretary of the syndicate. In the result the tribunal decided in favour of the syndicate.

Precautions against Cholera.

In several parts of France steps are being taken to prevent the importation of cholera by passengers or goods coming from infected countries. In conformity with a resolution adopted by the general council of the department of the Nord 30 military male nurses on Oct. 1st proceeded from Lille to the railway stations of Quiévrain and Jeumont, where they will do duty under the regulations for the prevention of cholera. Very strict measures are being taken with respect to goods brought from Naples. At Lyons the railway trains conveying emigrants from Italy to Havre are disinfected and their water-closets are examined.

Conference on Cancer.

The International Conference on Cancer met on Oct. 1st in the large amphitheatre of the Faculty of Medicine, 22 nations being officially represented. M. Doumergue, the Minister of Public Instruction, opened the proceedings, and among the more prominent members of the audience mention may be made of Professor Czerny of Heidelberg (president of the conference), Professor Bouchard (president of the French League against Cancer), Professor Landouzy, Professor Chantemesse, Professor Pozzi, Professor Widal, Professor Robin, Professor Delbet, Dr. Hallopeau, Dr. Metchnikoff, Dr. Kirchner of Berlin, Dr. E. F. Bashford of London, and Dr. Delage of the Institut. In his introductory address the Minister of Public Instruction, after some words of welcome to the members of the congress, and to the foreign delegates in particular, said that science had no frontiers, that feelings of international friendliness were increasing, and that a campaign against cancer had begun. Professor Czerny said that it was the French League against Cancer which had given rise to the international league. He then entered into technical details regarding cancer, a disease which was, in his opinion, on the increase; and, in the next place, he gave an account of the results which had been obtained since the year 1906, remarking at the same time that he hoped to see them improved upon. Professor Landouzy now spoke some words on behalf of the Faculty, and after him Professor Bouchard and all the foreign delegates successively addressed the meeting. Professor Delbet, general secretary of the conference, then read an interesting report in which he made a protest against unqualified persons professing to treat cancer; he firmly believed that this disease was curable, the proper treatment being a surgical operation performed in an early stage, and a similar opinion was expressed by many of the subsequent speakers. The conference adopted a proposal made by M. de Hansemann and Professor Delbet recommending unification of the technical terms relative to cancer which were employed in various countries. On Oct. 2nd the members of the conference were received by Dr. Henry de Rothschild at the Abbaye des Vaux de Cernay.

Oct. 3rd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The German Association of the Medical Press.

THE German Association of the Medical Press held its annual meeting on Sept. 11th in Berlin, Dr. Spatz, the editor of the *Münchener Medicinische Wochenschrift*, being in the chair. Nearly all the leading medical journals and reviews were represented, and it was stated that about 150 medical periodicals had established a connexion with the association. The principal subject of discussion was the question of reform in some details of medical journalism. The association took the view that the publication of articles on medical topics should as much as possible be reserved to the medical press, and that therefore *Festschriften*, special reports and year-books issued on behalf of medical institutions and hospitals were undesirable. Inaugural dissertations—i.e., the essays written by candidates for the degree of M.D.—would in future be reviewed only when an epitome had been sent to a medical journal. In original articles the addition of a bibliographical appendix should be avoided. Preliminary announcements on the results of new researches must contain only facts and should as much as possible be avoided. The editor of the *Deutsche Medicinische Wochenschrift* then gave some particulars relative to the black list of authors suspected of writing articles on behalf of manufacturing chemists, such articles being in reality advertisements of new pharmaceutical preparations. The black list has proved very efficacious, as the chemical manufacturers made less use of those authors since their contributions ceased to be inserted or reviewed in the journals belonging to the association. It was decided to complete the black list by adding the name of authors who were undesirable for other reasons than the above mentioned, and to prepare a similar list of journals whose respectability was doubtful. Advertisements of new remedies if containing obvious misstatements, and contributions by authors who had allowed previous publication of their articles, or portions thereof, in an ordinary newspaper, would be excluded from the journals belonging to the Association. This restriction was necessary, because some authors had written for the daily papers summaries of their experiences with Professor Ehrlich's new remedy. Dr. Posner, the editor of the *Berliner Klinische Wochenschrift*, presented a report on the proceedings of the International Association of the Medical Press at its meeting held during the International Medical Congress at Budapest. The influence of the German Association of the Medical Press is evidently being exerted to raise the general standard of medical journalism.

Professor Ehrlich's New Remedy.

Professor Ehrlich's remedy "606" continues to be of the highest interest for the medical profession, and the paper which he read at the Congress of the Association of German Medical Men and Naturalists was the most remarkable event of that congress. Reports of favourable results obtained with this preparation are frequent in the medical journals. Dr. Michaelis, writing to the *Berliner Klinische Wochenschrift*, reported that he had administered it in 110 cases. Of these patients seven suffered from primary ulcer which disappeared in from one to three weeks; in one case only a maculo-papular exanthem occurred but disappeared within 24 hours. In 15 cases there were secondary symptoms, which disappeared in in two days; papular exanthemata left only a small pigmentation after a period varying from 4 to 12 days. There were 22 cases of relapses from syphilis treated formerly by mercury; the Ehrlich treatment proved very efficacious in these cases also. A really marvellous effect was, however, observed in 33 cases in which, notwithstanding repeated administration of mercurials and iodides during several years, the symptoms did not disappear. The list included some patients who seemed likely to die within a short time, some who had for years been unable to work, and some who on account of fœtid ozæna were a burden to their family. There were patients with ulcerated gummata of the skin, the nose, the lips, and the tongue, as well as patients suffering from severe pains in the bones during the night; they all recovered within a few days. Professor Ehrlich was deeply impressed by the rapid recovery of patients who had hitherto derived no benefit from any kind of treatment. There were some cases of recovery from inveterate spinal and cerebral syphilis where undoubtedly a degeneration of the nervous substance had occurred. Of four cases of congenital syphilis in infants two were in a moribund state and died in 24 hours after the injection; the third, suffering from severe visceral syphilis, was free from symptoms on the sixth day after the injection, but unfortunately died from erysipelas on the fifteenth day. The fourth infant, who presented a maculo-papular exanthema, showed desquamation after 24 hours and the weight increased rapidly. In tabes and general paralysis the success was doubtful. A feverish reaction was sometimes totally absent and sometimes only very slight. In some cases the temperature rose to 39·2° C. Somewhat severe pain occurred as a rule for some hours. No obnoxious symptoms were ever observed, and the eyes, the kidneys, the heart, and the nervous system were never affected. It was not yet possible to say whether recovery would be permanent or not. Professor Ehrlich concluded from his experience that the new treatment was indicated in cases where treatment by mercury had proved inefficacious because the symptoms either did not disappear or else had a tendency to relapse, as well as in cases in which an idiosyncrasy against mercury existed or in which mercury could not be given because of

other organic diseases such as Bright's disease. Whether the new remedy was preferable to mercury for the treatment of recent syphilis was not yet ascertained. A contra-indication existed only in cases of severe cachexia.

Proposed Hospital for Juvenile Offenders.

A hospital for juvenile offenders is projected in Berlin. By the proceedings before the new children's courts it has become obvious that many of these culprits suffer from psychical and bodily abnormalities and hereditary taints. By adequate medical treatment and care a number of them may possibly be preserved from becoming irreclaimable criminals. Children until the age of 16 years are to be received in the hospitals.

Persistence of Enteric Fever Bacilli in the Urine.

Dr. Niepraschtz, a staff-surgeon of Wesel, writing to the *Zeitschrift für Hygiene*, reported that in the barracks of Wesel, which were fitted up with first-rate hygienic arrangements, epidemics of enteric fever broke out at irregular intervals. The water was supplied from the municipal waterworks, the disease was not prevalent in the town, but 91 cases, of which six were fatal, occurred within the last four years. It was ultimately found that a non-commissioned officer passed enteric fever bacilli in his urine. The man had typhoid seven years ago, but had completely recovered; but Widal's reaction continued to give a positive result.

Oct. 3rd.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Guido Baccelli and the Cholera in Rome.

THE Dean of Italian Medicine, discussing the situation with a colleague the other day, reiterated his conviction, already reported in THE LANCET, that cholera will effect no foothold as an epidemic in Rome. "Here," he added, "we have a double line of defence: that of the Divizione Generale della Sanità and that of the Divizione Sanitaria del Comune, both of them efficient in *personnel* and equipment, and both of them, in the day now passing, equal to all its exigencies in point of skill, experience, and courage. I have been present," he proceeded, "at all the visitations of cholera in the city and provinces for the last 56 years. One of these was at Tivoli, which lasted from 1854 to 1856 inclusive (36 months), but the worst was that in 1867 at Albano, perhaps the most destructive recorded in the annals of medicine. With such means of defence as science now commands the dread of cholera, as an epidemic, is quite without warrant. True, in several great centres the 'vibrione colerico' has acquired, so to speak, the right of citizenship, but it is never really formidable. Some years ago Finkler and Prior came to me with the request that I should examine their microscopic studies on 'cholera nostras.' I advised them to go to Genoa where Asiatic cholera had declared itself, that they might see the difference, if any, between the 'vibrio' of the one type and that of the other. They found little or none. For another reason all panic as to the invasion of cholera has no justification. Cholera, if I may say so, is an 'honest malady,' and betrays itself immediately by the virgula bacillus. As to so-called cases of 'cholera fulminante,' I am inclined to be sceptical. Even when the malady has declared itself in epidemic form such cases may be counted on one's fingers. My experience has been that in 95 patients out of every 100 cholera betrays its presence by premonitory diarrhœa. The moment this symptom is in evidence, let the physician be 'rung up' immediately, for in that stage science has many resources for the arrest or elimination of the *materies morbi*. Also, the case should be reported at once to the sanitary authority, if only to intensify the recognised precautions. These latter are chiefly to be sought in the ingesta, solid and liquid. The food should be thoroughly sound; fish to be freely partaken of, excluding the crustacea; vegetables also to be eaten with impunity, but only after boiling; personal cleanliness, particularly in the hands, is *de rigueur*, before sitting down at table. Wherever the water is suspected as to purity, it must be boiled before use. Wine should be taken, but moderately, and of a generous quality. Lastly, the *mens æqua*, and nothing more." As I write, the Assessore d'Igiene, Dr. Rossi-Doria, has issued his "notizia ufficiale" for the last 24 hours. "No new case of cholera in Rome. Only four suspected cases have been reported, but on examination they were found to have no relation with cholera. One was a case of pleurisy, the other three were cases of indigestion. All the patients at the Lazzaretto are doing well; also the female case at the Tor di Valle."

The Health of Naples.

At 7 P.M. on Sept. 30th the official bulletin announced 17 cases with only five deaths. The improvement in the sanitary situation continues, slow but steady. The mortality has sunk from the 58 per cent. of Sept. 29th to 30 per cent. on the 30th. As to the "movimento" at the harbour, from the day on which it was declared "infected," the steamers carrying goods have been 74, the number of passengers 4000, while eight sailing vessels have had to put back to sea without "operazioni di commercio." Among the exports prohibited are carpets, articles of domestic use, and rags.

The Health of Genoa.

Here the sanitary authority reports the "salute pubblica" as excellent under every heading. From Sept. 30th at 2 P.M. there were recorded only two deaths from ordinary maladies within the preceding 36 hours—an infant and an adult male—while the number of births had risen to 30.

Oct. 1st.

NOTES FROM INDIA.

(FROM OUR OWN CORRSPONDENTS.)

Plague.

THE plague reports for the week ending August 20th for all India show a total mortality of 1046. The Bombay Presidency returned 350 deaths, the Central Provinces 114, and Mysore State, the United Provinces, Rajputana, and Ajmer Merwara all over 90 deaths each. For the week ending August 27th the total mortality for all India was 1325. There were 549 deaths from plague in the Bombay Presidency, 269 in the United Provinces, and 141 in Hyderabad State. On the recommendation of the Governments of India and Madras the Mysore State have sanctioned the use of kerosene oil emulsion for the disinfection of plague-infected houses. The Sanitary Commissioner of Mysore is, however, of opinion that kerosene oil emulsion is useful as a destroyer of fleas, that the Madras emulsion is cheaper and quite effective, that disinfectant powers are not claimed for these emulsions, that they cannot be considered to be of much value except in *pucca* (stone-built) houses, and that their use, like the use of disinfectants generally, is limited by the fact that they cannot affect the fleas or their ova when lodged in the cracks of the walls of mud-built huts.

Deaths Caused by Wild Animals.

A return showing the number of persons killed by wild animals in India is annually compiled and issued by the Government of India. The total number for 1909 was 2607, which is an increase compared with the preceding five years. The increase is specially noticeable in the number of deaths attributed to tigers in Madras, where the figures rose from 170 in 1908 to 291 in 1909, the districts of Coimbatore and Vizagapatam being the most dangerous. In Madras Presidency the number of deaths due to leopards rose from 45 in 1907 to 91 in 1909. In Bengal the number of deaths caused by tigers fell from 455 in 1908 to 303. There was also a decrease in Hazaribagh mainly due to the payment in 1908 of special rewards of Rs. 50 (£3 6*s.* 8*d.*) for every tiger killed within certain specified areas. The number of deaths from wolves in Bengal fell from 184 in 1908 to 167, but the deaths in Hazaribagh from this cause rose from 75 in 1908 to 95, notwithstanding that a special reward of Rs. 20 was offered for every wolf killed within certain areas. The reward has now been raised to Rs 50. The number of wild animals destroyed was 17,449, or about 500 less than the number reported in 1908. Nearly 500 leopards, 1473 tigers, 2850 wolves, and over 2000 bears were killed in the course of the year. The total number of snakes killed rose from 70,732 in 1908 to 88,503 in 1909.

Sept. 4th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Disease in Queensland.

Dr. Anton Breinl, director of the Tropical Diseases Hospital at Townsville, has reported that he has found a good many cases of beri-beri, chiefly among coloured people. Ankylostomiasis is fairly common in North Queensland. In one quarter of Cairns, known as "Sandy Gallows," Dr. Breinl found evidence of earth-eating in every house. Cane-cutters suffer from an affection locally known as "sand-worm," which manifests itself in the form of ulcer on the inner aspect of the foot and in which no parasite can be demonstrated. Dr. Breinl does not consider the occupation of cane-cutting unsuitable for white labourers, but suggests further investigation into blood conditions before and after working through the season.

Gaol Surgeons.

At Ballarat the medical man acting as gaol surgeon died recently and the Government sought to fill the position by inviting tenders from the medical profession. This action highly incensed the resident practitioners of the district, who agreed unanimously that none of their number would accept the position under £150 per annum. The Government has now decided that the medical officers of the lunatic asylum shall also be gaol surgeons.

Bush Nursing.

The first meeting of the Provisional Federal Council for the Australian Order of District Nursing was held at Government House, Sydney, on July 30th, and there were present the Governor-General and Lady Dudley, the Governor of Victoria and Lady Gibson Carmichael, the Governor of Tasmania (Sir H. Barron), Sir J. Carruthers and Professor Anderson Stuart (New South Wales), Dr. Newlands (South Australia), and Mr. A. W. Meeks (Federal Honorary Treasurer). The draft constitution was approved and various committees were formed to consider finance and questions of regulations. The scheme still fails to awaken any popular enthusiasm in any of the States, while the attitude of the medical profession is generally apathetic and that of the nursing organisations mildly hostile.

New Hospital.

On August 14th a new hospital was opened in Brisbane by the Governor of Queensland after being blessed by his Eminence Cardinal Moran. The institution will be called the Mater Misericordiæ Hospital and will be under the direction of the Sisters of Charity. The Order has already established St. Vincent's Hospital, Sydney, and St. Vincent's Hospital, Melbourne, the latter being a clinical school in the University of Melbourne.

Lady Talbot Milk Institute.

The committee of this undertaking, which was founded some two years ago to supply infants in poorer suburbs of Melbourne with pure milk during the hot months, finds itself in serious financial difficulties, and has appealed to the State Government for assistance. When the scheme was first mooted it was clearly foretold by expert critics that such a result was inevitable, and it has not taken long to come about. The Government, while disposed to render financial aid, has appointed a medical man and a departmental officer to examine the claims and working of the institute, and report thereon.

Radium.

The movement in Sydney to provide a supply of radium for the hospitals by public subscription has been taken up with enthusiasm by the press. Miss Nelly Stewart, a well-known operatic artist, has given a special matinée in aid of the fund, and a considerable sum of money is likely to be raised.

Ninth Australasian Medical Congress.

The ninth session of congress will be held in Sydney from Sept. 18th to 23rd, 1911, the President being Dr. F. Antill Pockley. The Presidents of sections are as follows:—Medicine: Mr. G. C. Hayward, Adelaide. Surgery: Mr. G. A. Syme, Melbourne. Obstetrics and Gynæcology: Dr. Rothwell Adam, Melbourne. Anatomy, &c.: Dr. E. H. Embley, Melbourne. Pathology and Tropical Medicine: Dr. Wilton Love, Brisbane. Public Health: Mr. J. W. Hope, Fremantle. Ophthalmology: Dr. J. W. Barrett, Melbourne. Neurology and Psychiatry: Mr. W. Beattie Smith, Melbourne. Children: Dr. A. Jeffreys Wood, Melbourne. Naval and Military: Colonel C. S. Ryan, Melbourne. Dermatology and Radio-Therapy: Dr. H. Lawrence, Melbourne. Laryngology, &c.: Dr. W. N. Robertson, Brisbane. The subject for general discussion by the Congress has been announced to be "Vaccine Therapy."

August 25th.

Obituary.

FULGENCE RAYMOND, M.D.,

PROFESSOR IN THE FACULTY OF MEDICINE OF PARIS; PHYSICIAN TO LA SALPÊTRIÈRE.

THE medical profession of France and neurologists the world over have sustained a serious loss by the death, in his sixty-seventh year, of Fulgence Raymond, professor in the Faculty of Medicine of Paris, and head of the clinic of nervous diseases at the Salpêtrière. Our Paris correspondent who makes the announcement gives details of his early career. It is less than a year since he was present, as a distinguished foreign guest, at the opening of the new out-patient department at the National Hospital for the Paralysed and Epileptic in Queen-square, London, thus evincing his constant interest in the work of institutions concerned with nervous disease, and little more than two years since he delivered a noteworthy lecture before the Royal College of Physicians of London on Premature Physiological Senescence localised to certain Organic Systems. The reproach has sometimes been raised that our continental *confrères* tend to ignore somewhat the labours of other workers in the neurological field than those who happen to be of their own country or nationality, but those who are acquainted with the numerous articles, papers, monographs, and volumes that have come from his pen know that Professor Raymond was as familiar with the neurological literature of England and America as with his own. He was catholic in his interests and cosmopolitan in his outlook, as befitted a great teacher. Here in England, therefore, where he had many friends, we can sympathise the more readily with our colleagues of the Parisian School of Medicine.

At the close of the lecture above referred to Professor Raymond said: "And at the present time can you not be justly proud of your brilliant phalanx of neurologists, who would not forgive me were I to sing their praises?" The compliment might with greater justice be returned, for the presence of so many distinguished pupils of the great Charcot has made the Société de Neurologie of Paris the premier neurological society of the world. Among them Professor Raymond held a pre-eminent place, inasmuch as he was called in 1894 to be Charcot's successor as clinical professor of nervous diseases at the Salpêtrière. How ably he filled a difficult position, and how nobly he maintained its traditions a constant stream of visiting strangers from all parts of the world can bear witness. It was said of him at the time: "Nous sommes persuadés que Fulgence Raymond occupera dignement la chaire de clinique nerveuse à laquelle viennent de l'appeler, à la presque unanimité, les professeurs de la Faculté de Médecine; qu'il continuera les traditions de notre illustre Maître, c'est à dire que les médecins étrangers trouveront à la Salpêtrière, de sa part, le même bon accueil; qu'il saura attirer autour de lui des étudiants laborieux, en mettant généreusement à leur disposition les richesses scientifiques de la clinique de la Salpêtrière. Et nous espérons qu'il poussera encore au delà les traditions hospitalières du Maître." These wishes were completely fulfilled. That the school of the Salpêtrière has maintained its brilliant reputation is due in no small measure to the quiet, modest, unremitting labours of Professor Raymond.

His literary activity was as remarkable as his scientific capacity. There appeared annually from his clinic volumes of *Leçons sur les Maladies du Système Nerveux* from 1894 to 1902, in which were published many articles that are models of clinical insight and scientific description. To the very end neurological journals, such as the *Archives de Neurologie*, *Revue Neurologique*, and *L'Encéphale*, were enriched by communications from him bearing on every department of nervous disease. His work on systematised scleroses of the spinal cord, on pseudo-tabes, Friedreich's disease, myopathy,

and hemichorea—to mention but a few—are contributions to our knowledge of permanent value. In collaboration with his colleague Professor Janet there appeared in 1898 a volume on *Névroses et Idées Fixes*, and in 1903 another on *Les Obsessions et la Psychasthénie* that have proved a rich treasure of scientific information on a most obscure and complex department of neurology. While perhaps the name of Raymond will not be associated with any strikingly original discovery in the science of which he was such a master, his fame as a teacher will remain wherever there are pupils of his to carry on his work. He delighted to associate with men younger than himself, to collaborate with them and aid them to the utmost of his ability, therein revealing his knowledge of the secret of clinical success. Those who have ever "assisté" at the meetings of the Neurological Society of Paris will appreciate the loss it has sustained, not only by the recent lamented death of Professor Brissaud, but now also by that of Professor Raymond, and will find it difficult to believe that his genial face and figure will be seen there no more, nor his voice heard in the councils and discussions of the society of which he was so long one of the most able and faithful supporters.

Sir Dyce Duckworth has sent us the following tribute to Professor Raymond's memory:—"The death of this distinguished physician has caused a deep sense of regret in the hearts of all who had the privilege of his acquaintance. As the successor of Charcot in the clinic of the Salpêtrière he filled a chair which has long been regarded as one of the most prominent teaching centres of neurology. Fulgence Raymond, however, was totally different in mind and manner from his great predecessor. Although, like him, he was a close and painstaking student of disease, with a mind set on precision and the revelation of the true inwardness of morbid processes, he was singularly calm and undemonstrative, and he never posed in public or private. Others will tell of his work and method, and not less of the splendid appreciation in which he was held by his colleagues and numerous pupils. None who heard him deliver his admirable lecture on Familial Diseases in the Royal College of Physicians of London in June, 1908, when he represented the French side of the *Entente cordiale médicale*, can forget that interesting occasion. His visit to London gave him great pleasure, and the honorary D.Sc. degree conferred upon him by the University of Oxford at that time he regarded as the supreme honour of his life. Last year he was an invited guest to the opening of the new out-patient department of the National Hospital for the Paralysed and Epileptic, Queen-square, and was much gratified at his kindly reception by the late King who conversed with him for some time.

Raymond's death is a serious loss to the Parisian School of Medicine. His personal qualities were most engaging. In his character he blended in a singular manner the elements of modesty, sweetness, and simplicity with great mental power. No one could know him in public or private life without loving him. Happy in his professoriate, in his practice, and in his domestic life, both in Paris and at his country home, he has been taken from a sorrowing band of relatives, colleagues, and devoted pupils. R.I.P."

JOSEPH HIGHAM HILL, M.D. BRUX., F.R.C.S. EDIN., L.R.C.P. EDIN., L.S.A.

WE regret to announce the death of Dr. J. H. Hill, which took place at his residence, Bedford-square, Bloomsbury, London, W.C., on Sept. 28th. He was a well-known practitioner in the district in which he lived and as a public servant did much good work.

He was educated at Glasgow, London, and Brussels, qualifying as a Licentiate of the Royal College of Physicians of Edinburgh in 1867. In the following year he became a Licentiate of the London Society of Apothecaries and obtained the Fellowship of the Royal College of Surgeons of Edinburgh in 1872. In 1879 he took, with honours, the M.D. degree of Brussels. He was a Government medical inspector of emigration at the Port of London, and among the positions which he held at various times were examining medical officer of the Royal Reserve Battalions of London, Government medical inspector in the United Kingdom for the United States of America, examiner in surgery for the United States Army and Navy pensioners, and Government medical officer at Sydney, New South Wales. His hospital appointments included those of senior medical officer, and medical superintendent of St. Pancras Infirmary, senior resident physician and resident surgeon to the Royal Free Hospital, and house surgeon to the Glasgow Maternity Hospital. He was the author of "An Analytical Report of Coroners' Inquests," and from time to time contributed to the medical journals. One of the subjects with which he was particularly interested was the importation and disinfection of rags, and in 1888 contributed to our columns with regard to this particular department of his work.

Medical News.

HOSPITAL DINNERS.—*Charing Cross Hospital.*—The annual dinner of the past and present students of this hospital was held on Oct. 3rd at the Criterion Restaurant, Mr. P. L. Daniel occupying the chair. He was supported, amongst others, by Professor William Osler, Dr. F. W. Mott, Mr. Stanley Boyd, Mr. Herbert Waterhouse, and Dr. T. W. Eden. After the loyal toasts Mr. Daniel, in proposing the toast of "The Hospital and School," referred to the *personnel* of the hospital staff, of which all connected with the institution might justly be proud. Mr. Waterhouse, in responding to the toast, drew attention to the successes of Charing Cross men at the examinations. He reminded those present also that they had been fortunate enough to obtain a money grant from the Board of Education, which it was hoped might mean that those who for so many years past had given their best teaching for nothing would get some sort of recompense. Dr. Eden made an excellent and amusing speech in proposing the toast of "The Visitors," to which Professor Osler replied. Professor Osler congratulated the school on its successes and the hospital staff on its scientific administration. He thought that a small school had decided advantages over a large school, and one of the most important of these was that the teacher was in closer contact with his pupil. He referred to the splendid gratuitous service of the medical staff at a hospital, only to be rewarded, perhaps, by damaging accusations of carrying out "the ghastly practice of vivisection." He asked where British medicine would have been if it had not gained so much of its advances from a series of properly conducted scientific experimentations. He thought it would be a bad thing for the progress of medical science if methods of gaining knowledge, which were of the greatest service in stamping out disease, were to be prohibited on the representations of ignorant persons. Mr. Stanley Boyd proposed the health of the chairman, and said they were very proud to claim him as a Charing Cross man, to which Mr. Daniel replied in suitable terms.——*Middlesex Hospital.*—The annual dinner of the past and present students of the hospital took place on Oct. 3rd, Mr. T. H. Kellock being in the chair. The toast of the Middlesex Hospital and Medical School was responded to by Viscount Duncannon, Dr. H. Campbell Thomson (Dean), Mr. J. Bland-Sutton, and Mr. B. S. Simmonds (Broderip scholar).——*St. Bartholomew's Hospital.*—The annual dinner was held in the Great Hall of the hospital on Oct. 3rd, Mr. C. B. Lockwood, surgeon to the hospital, being in the chair. The dinner was well attended. A plain, clear speech by Mr. Lockwood, setting out at the same time the strong position of St. Bartholomew's Hospital and its needs in certain directions, was replied to by Lord Sandhurst, the treasurer of the hospital, who promised on behalf of the governors that no efforts should be spared to keep the institution as a model hospital and school. Dr. Norman Moore proposed the health of the guests in witty terms, coupling the toast with the name of Sir Clifford Allbutt, who replied. Mr. Bruce Clarke proposed the health of the chairman.——*St. George's Hospital.*—The annual dinner was held on Oct. 1st at Prince's Restaurant, Piccadilly, Mr. G. R. Turner, surgeon to the hospital, being in the chair. The dinner was extremely well attended. Mr. Turner, in an excellent speech, showed that the hospital under the present conditions continued to attract a very high class of student, although their numbers were necessarily smaller than when the preliminary scientific subjects were all dealt with at St. George's. He spoke strongly of the way in which the Medical School of the hospital had been treated by the authorities of the University of London, but claimed none

the less great vitality for the institution. The Dean, Dr. E. I. Spriggs, in reply, was able to confirm Mr. Turner's words, and communicated to the audience a long list of honours obtained by St. George's students. The treasurer, Mr. A. W. West also replied. Other speeches were made by Mr. Brudenell Carter, who made an allusion of marked kindness to THE LANCET, by Dr. Squire Sprigge, Dr. J. Blumfeld, Dr. Sherwood, and Dr. G. P. Humphry.——*St. Thomas's Hospital.*—The annual dinner of the past and present students was held on Oct. 4th at the Hotel Cecil, Mr. W. F. Haslam occupying the chair. Amongst those present were Mr. Butlin, Sir T. Chavasse, Alderman Sir Thomas Crosby, Sir Alfred Keogh, Sir William Leishman, Sir James Porter, and Mr. J. G. Wainwright. After the toasts of "The King" and "The Royal Family" had been given, Mr. Haslam proposed "The Hospital and School," referring to the irreparable loss they had sustained in the death of Mr. Clutton and the retirement of Dr. Sharkey from the hospital staff. It was, however, a consolation to know that Dr. Sharkey was still to remain lecturer on medicine in the school. The toast was responded to by the treasurer, Mr. Wainwright and Dr. H. G. Turney (dean). Dr. T. D. Acland proposed the toast of "The Visitors," associating with it the names of Mr. Butlin, Sir T. Chavasse, Sir James Porter, Sir Alfred Keogh, Sir W. Leishman, and Alderman Sir Thomas Crosby. Mr. Butlin responded, referring to the feeling of affection which he had for St. Thomas's Hospital next to his own hospital. The health of the chairman was proposed by Mr. G. H. Makins, and in responding Mr. Haslam insisted on the grave omission in the programme, which contained no provision for toasting the honorary secretaries of the dinner. He repaired this by giving their healths himself, a toast which was drunk with great enthusiasm.——*St. Mary's Hospital.*—The annual dinner of past and present students was held at Princes' Restaurant on Oct. 3rd. Mr. J. Ernest Lane was in the chair, and there were 151 present. The chairman, in proposing the toast, "St. Mary's Hospital and Medical School," deplored the death of Mr. Henry Harben. The school for which he had worked so devotedly was very conscious of its irreparable loss. Mr. Lane had joined St. Mary's 35 years ago, and this, he said, was the thirty-fifth annual dinner he had attended. The toast was replied to by Sir John Broadbent, Dean of the Medical School. He dwelt on the obstacles now placed in the path of the student who desires a doctor's degree, and hoped for the removal of what was seriously hampering the development of the London schools of medicine. One of the privileges of his predecessors for the last six years was to congratulate a student of St. Mary's on obtaining the gold medal of the London University in either the M.B. or M.D. examinations. It was his this year, and he hoped it would become an annual custom. In proposing "The Visitors," Sir Almroth Wright began by a confession of ignorance of the ritual of such occasions, but concluded in orthodox and technical manner. Sir Arthur Conan Doyle, who in the afternoon had spoken of Romance in Medicine, now turned the tables, and in responding told of Medicine in Romance. Certain diseases were invaluable to the novelist in the destruction of the villain and the lower forms of life around which plots turn. His favourite weapons were phthisis and brain fever. He also related the criticism of a Cornish boatman: "I've read them tales of yours," said he, "and how Sherlock Holmes fell over the cliff. But I'm thinking if Holmes wasn't killed he must have been injured, because he's never been the same man since." The toast was also replied to by Surgeon-General W. L. Gubbins, who spoke with admiration of Sir Almroth Wright's work in typhoid inoculation. The health of the chairman was proposed by Dr. A. P. Luff, who paid a graceful tribute to Mr. Lane.

A NEW LYING-IN WARD IN ST. THOMAS'S HOSPITAL.—The governors of St. Thomas's Hospital have at considerable expense prepared a ward specially for lying-in cases. The authorities, being anxious to work in sympathy with general practitioners, are prepared to accept for treatment in this ward cases of anticipated difficult labour if strongly recommended for admission by a general practitioner when the circumstances of the home make hospital treatment desirable. General practitioners who may wish to avail themselves of the lying-in ward, should give due notice and find out whether there is a vacant bed for the cases in which they are interested.

ST. BARTHOLOMEW'S HOSPITAL.—The examination for the entrance scholarships which was held on Sept. 22nd and succeeding days has resulted in the following awards: Entrance Scholarship in Arts (value £100), David Constantin of the Royal College of Mauritius. Jeaffreson Exhibition in Arts (value £50), Richard G. Morgan of Newport Intermediate Boys' School. Senior Entrance Scholarships in Science (value £75 each), G. L. Kynes, B.A., of Pembroke College, Cambridge, and R. Stansfeld, B.A., of St. John's College, Cambridge. Junior Entrance Scholarship in Science (value £150), F. G. L. Barnes of St. Bartholomew's Hospital and H. L. Cronk of Jesus College, Cambridge, equal.

GUY'S HOSPITAL MEDICAL SCHOOL.—The following entrance scholarships and certificates have been awarded:—Senior Science Scholarship for University Students (value £50), Ronald C. Oxanne, B.A., Hertford College, Oxford. Junior Science Scholarships: (value £150) Arthur Lisle Punch, Preliminary Science Class, Guy's Hospital; (value £60) Alfred George Simmins, Preliminary Science Class, Guy's Hospital. Certificates: John Frank Herbert Stallman, Preliminary Science Class, Guy's Hospital; Olaf Gleeson, Walthamstow Technical Institute. Entrance Scholarships in Arts: (value £100) Alexander Beckett Bond, Bradfield College; (value £50) John Arnold Molony Alcock, Radley College. Equal Certificates: Samuel Vidot, St. Louis College, Seychelles; Albert Victor Wood, Wolverhampton Grammar School.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The following awards were announced at the opening of the winter session at St. George's Hospital on Oct. 1st: Pollock Prize in Physiology and Brodie Prize, G. H. Varley; Webb Prize in Bacteriology (value £30), R. F. Jones; Entrance Scholarships, E. F. W. Grellier, Downing College, Cambridge, and W. E. Waller, University College, Oxford, equal; Allingham Scholarship, L. Colledge; William Brown Exhibition (value £100), E. W. M. H. Phillips; William Brown Exhibition (value £40), C. H. S. Frankau; Brackenbury Prizes in Medicine and Surgery (total value £60), N. W. Berry; Treasurer's Prize (value 10 guineas), J. H. Newmarch; Thompson Medal, L. W. K Scargill; Henry Charles Johnson Prize in Anatomy, Percy Whitehead; Anæsthetics Prize for practical work of anæsthetics clerks, J. Ellison; Sir Charles Clerke's Prize for Good Conduct, Maurice Burnett; Pollock Prize, 1909-10, Ernest Scott.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—The following is a list of awards for the past winter and summer sessions:—Huxley Scholarship (value 50 guineas), R. V. Bevan. Universities Scholarship (value 50 guineas), C. J. Marshall. Governors' Clinical Gold Medal and Llewellyn Prize (certificate and £25), N. C. Lake. William Travers Prize (certificate and £15), B. F. Eminson. Huxley Prize (certificate and £3 3*s.*), A. E. Hallinan. Golding Prize (certificate and £2 2*s.*), A. C. S. Cottam. The following prizes and certificates have also been awarded:—Anatomy (senior): A. E. Hallinan (prize), C. E. Williams (certificate) and J. H. Paget (certificate). Anatomy (junior): A. C. S. Cottam (certificate). Biology: F. J. Hallinan (prize), G. S. Marshall (certificate), H. Williamson (certificate), and E. S. Rowbotham (certificate). Chemistry: A. T. Dally (prize), F. J. Hallinan (certificate), and H. Williamson (certificate). Physics: F. J. Hallinan (prize), H. Williamson (certificate), and A. T. Dally (certificate). Physiology (senior): A. E. Hallinan (prize). Physiology (junior): A. C. S. Cottam (prize), H. V. Morley (certificate), and H. Wardill and E. V. Jones (equal certificates). Medicine (senior): B. F. Eminson and R. F. Eminson (equal prizes), and N. C. Lake (certificate). Surgery (senior): N. C. Lake (prize), B. F. Eminson (certificate), and R. F. Eminson (certificate). Psychological Medicine: T. Beaton (prize) and B. F. Eminson (certificate) (*proxime accessit*). Ophthalmology: N. C. Lake (prize), T. Beaton (certificate), and B. F. Eminson (certificate). Midwifery: B. F. Eminson (prize). Gynæcology: T. Beaton (prize). Pathology: I. M. Davies (prize), A. Evans (prize from lecturer), W. E. Hallinan (certificate), and A. B. Rosher (certificate). Public Health: B. F. Eminson (prize) and W. P. Harrison (certificate). Therapeutics: A. E. Hallinan (certificate). Forensic Medicine and Toxicology: I. M. Davies (certificate).

GUILD OF ST. LUKE: BIRMINGHAM WARD.—The annual festival service will be held on Tuesday, Oct. 18th, at 4.15 P.M., in the Cathedral, Worcester, when the sermon will be preached by the Very Rev. the Dean of Worcester. All medical practitioners are cordially invited to attend.

AT a meeting to be held in the Lecture Hall of the Pharmaceutical Society, at 17, Bloomsbury-square, London, W.C., on Tuesday, Oct. 11th, at 8 P.M., Mr. E. W. Lucas, F.I.C., F.C.S., and Mr. F. C. J. Bird will communicate a paper on the Fixed Oils, Fats, and Waxes of the British Pharmacopœia. Medical men are cordially invited to attend.

FREEDOM OF THE BOROUGH OF PRESTON FOR DR. R. C. BROWN.—We have on several occasions referred to the munificent gifts which Dr. Brown has from time to time made to the medical charities of Preston, and we are glad to notice that the freedom of the borough has now been conferred upon him. Dr. Brown, who is one of the oldest and most esteemed citizens of the borough, was born in 1836. The presentation ceremony was performed in the Guildhall on Sept. 29th, when he received a silver casket containing the resolution which was passed last March at a special meeting of the council:—

> In recognition of the eminent services rendered by him to the town, for his generous benefactions for the alleviation of pain and suffering, and by the kindly and effective interest taken by him in the welfare of the community, and to worthily mark the esteem in which he is held by the inhabitants of the borough.

Dr. Brown, who is consulting medical officer to the Preston Royal Infirmary, defrayed the expense of building and equipping a new operating theatre in that institution, which cost about £2700. He also presented the infirmary with a beautiful organ, a piano, and a pianola, provided a billiard-room and recreation-rooms equipped with facilities for games for the use of members of the staff, and, in addition, defrayed the cost of a conservatory for convalescent patients, revolving summer-houses for open-air treatment, and a complete X ray apparatus.

PROPOSED MEMORIAL TO THE LATE MISS FLORENCE NIGHTINGALE: A COUNTER PROPOSAL.—The movement for the establishment of a memorial in Liverpool to perpetuate the name and work of the late Miss Florence Nightingale has now assumed a definite form. The Queen Victoria District Nursing Association, which has the matter in hand, has decided that an urgent necessity exists for another district nursing home, and that such a scheme will form a fitting memorial of the valuable and enduring services which the deceased lady gave to nursing throughout the world, and to Liverpool in particular. To her the nursing movement in this city owed its initiation, and it was her direct encouragement that led the late Mr. William Rathbone to found the Queen Victoria District Nursing Association. The work has now grown to such an extent that an additional home is said to be urgently needed to enable the association to cope with the demands made upon it. To bring the matter to a practical issue the committee of the association appointed a small deputation to wait upon the Lord Mayor and request him, as president of the association, to call a public meeting for the inauguration of a memorial fund. The deputation recently met the Lord Mayor at the town hall, and after hearing a statement from the members of the deputation, his lordship acquiesced in the advisability of calling a meeting of the general public with the object of raising a fund for the building and maintenance of an additional nursing home to be named the "Florence Nightingale Home." The meeting was fixed by the Lord Mayor for Thursday, Oct. 13th, at the town hall. On the other hand, a strong feeling exists that the occasion is opportune for the establishment of better provision for the necessitous condition of nurses of advancing years. There is no burking the fact that the demand for nurses over the age of 40 years is becoming a diminishing quantity. Many of these deserving persons are paying the annual premium on their policies with the Royal National Pension Fund, and as years go on the difficulty in finding the means for continuing payment up to 55 years of age increases, and, sad to say, in many instances becomes impossible. This latter difficulty has suggested to many philanthropic people that the memorial might take the form of a "Florence Nightingale Home of Rest" for nurses of advancing years. There is much to be said in favour of such a deserving object, and it is to be hoped that the matter will be brought up at the town's meeting as a corollary to the suggested "Florence Nightingale Home." A "home of rest" would be something to look forward to by those who have no friends, and who have given the best years of their lives in the cause of suffering humanity.

Dr. Robt. Marshall, medical officer of health of Douglas, Isle of Man, has been returned at the head of the poll to the House of Keys. His programme was largely one of public health.

MANCHESTER ROYAL INFIRMARY.—A meeting of the Old Residents' Club will be held at the Midland Hotel, Manchester, on Saturday, Oct. 15th, at 6.30 P.M. This meeting will be followed at 7 P.M. by a dinner, at which Mr. F. A. Southam will preside. Any old resident who has failed to receive a notice is requested to apply to the secretaries of the club at the Royal Infirmary, Manchester.

THE Anniversary Lecture of the American Academy of Ophthalmology and Oto-Laryngology was delivered at Cincinnati, Ohio, on Sept. 19th last by Mr. Sydney Stephenson of London, who took as his subject "Sloughing Corneæ in Infants: an Account based upon the Records of 31 Cases." Mr. Stephenson was presented with a suitably inscribed gold medal by the Academy.

WELSH MEDICAL DINNER.—The seventh annual Welsh medical dinner was held on Sept. 30th, Mr. Robert Jones being in the chair. The Royal toasts having been drunk to the singing of the National Anthem and the anthem "Tywysog Cymru," the chairman proposed "Meddygon Cymraeg a Meddygon Cymru." The toast of the visitors was responded to by Mr. H. T. Butlin, Sir W. Allchin, and Mr. Goscombe John. The dinner ended with "Hen Wlad fy Nhadau" sung in chorus.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ANDERSON, G. W., M.B. Toronto, has been appointed Clinical Assistant to the Chelsea Hospital for Women.

CARROLL, T. P., M.B., B.Ch. R.U.I., has been appointed Medical Officer of the Kilmeaden Dispensary District, Waterford.

DEVINE, HENRY, M.D., B.S. Lond., M.R.C.P. Lond., has been appointed Senior Assistant Medical Officer at the West Riding Asylum, Wakefield.

DOBSON, J. R. B., M.R.C.S., L.R.C.P. Lond., B.S. Lond., has been appointed House Physician at the South Devon and East Cornwall Hospital, Plymouth.

EDMOND, WILLIAM SQUARE, F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Resident Medical Officer at the London Temperance Hospital.

HAGAR, F. C., M.D., C.M. Ont., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

HATHERLEY, S. O., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health to the Urban District Council of Swinton, Rotherham.

HERON, A. G., M.D. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Dromara District of the county of Down.

HEWER, H. M., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Market Bosworth District of the county of Leicester.

KNOX, ROBERT, M.D. Edin., M.R.C.S., L.R.C.P. Lond., has been appointed Director of the Electrical and Radio-Therapeutic Department at the Cancer Hospital.

MORGAN, D. L., M.B. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Pembroke District of the county of Pembroke.

PEACOCK, W. E., M.D., B.S. Durh., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

PETERSEN, H. C., M.D. U.S.A., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

PRICE, A. R., M.B., Ch.B. Edin., has been appointed Medical Officer to the Cardiff Board of Guardians.

SHAW, G., M.B. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Alyth District of the counties of Forfar and Perth.

SIM, J. BROWN, M.B., C.M. Glasg., has been appointed District Medical Officer by the Nottingham Board of Guardians.

SOMERVILLE, H., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Harrold District of the county of Bedford.

TRINDER, A. P., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Wadebridge District of the county of Cornwall.

WOODWARK, A. S., M.D., M.R.C.P. Lond., has been appointed Junior Curator and Demonstrator of St. Bartholomew's Hospital Museum.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and lodging.

BEDFORD COUNTY HOSPITAL.—House Physician. Salary £60 per annum, with apartments, board, and washing.

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL, Edmund-street.—House Surgeon for six months. Salary at rate of £70 per annum, with board, lodging, and washing.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Two House Surgeons for six months. Salary at rate of £75 per annum, with board and residence.

BRADFORD POOR-LAW UNION HOSPITAL AND WORKHOUSE.—Assistant Resident Medical Officer, unmarried. Salary £130, with rations, apartments, and laundry.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—Resident Medical Officer, unmarried. Salary £160 per annum, with rooms, coals, gas, and attendance.

BRISTOL ROYAL INFIRMARY.—House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—Resident House Surgeon. Salary £50 per annum, with board and residence. Also Registrars and Clinical Assistants.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £75 per annum, with board and lodging.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £60 per annum, with board, apartments, and laundry.

COLCHESTER, BOROUGH EDUCATION COMMITTEE.—Assistant School Medical Officer (female). Salary £250 per annum.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon, also House Physician. Salary in each case £80 per annum, with board, washing, and residence.

DENBIGH, DENBIGHSHIRE INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with board and lodging.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—House Surgeon. Salary £120 per annum, with board, apartments, and washing.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50, with board, residence, and laundry.

HALIFAX, ROYAL INFIRMARY.—Second and Third House Surgeons, unmarried. Salary £100 and £80 respectively, with residence, board, and washing.

HALIFAX UNION POOR-LAW HOSPITAL.—Resident Medical Officer. Salary £110 per annum, with apartments, rations, and washing.

HAMMERSMITH INFIRMARY AND WORKHOUSE, Ducane-road, Wormwood Scrubs, W.—Assistant Medical Superintendent. Salary £100 per annum, with board, lodging, washing, and attendance.

HAMPSTEAD GENERAL HOSPITAL.—House Physician and House Surgeon for six months. Salary at rate of £70 per annum, with board and residence.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with rooms, board, and washing.

HELLINGLY, EAST SUSSEX COUNTY ASYLUM.—Assistant Medical Officer and Pathologist, unmarried. Salary £250 per annum, with board, lodging, washing, &c.

HÔPITAL FRANCAIS, 172, Shaftesbury-avenue, W.C.—Second Resident Medical Officer, unmarried. Salary £50 per annum, with full board and laundry.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Fourth Anæsthetist. Salary £15 15s. per annum. Also House Surgeon, unmarried, for six months. Salary £30, with board, residence, &c.

IPSWICH, BOROUGH OF.—Assistant Medical Officer of Health. Salary £250 per annum.

JERSEY INFIRMARY AND DISPENSARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and attendance.

KETTERING AND DISTRICT GENERAL HOSPITAL.—Resident Medical Officer, unmarried.

KING EDWARD VII. SANATORIUM, Midhurst, Sussex.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and attendance.

KING'S COLLEGE HOSPITAL, London, W.C.—Assistant Surgeon.

LIVERPOOL, STANLEY HOSPITAL.—Senior House Surgeon. Salary £90 per annum. Also Two Junior House Surgeons. Salary £70 and £60 per annum respectively.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £80 per annum, with board, residence, &c.

MANCHESTER, ANCOATS HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board, &c.

MARGATE, ROYAL SEA BATHING HOSPITAL FOR SURGICAL TUBERCULOSIS.—Resident Surgeon. Salary at rate of £80 per annum, with board and residence.

NEWCASTLE-UPON-TYNE CITY ASYLUM, Gosforth.—Junior Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, and laundry.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Assistant House Surgeon for six months. Salary £20, with board, lodging, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Honorary Dental Surgeon. Also House Physician and House Surgeon for six months. Salary in each case at rate of 50 guineas per annum, with board and residence.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Assistant Surgeon. Also Junior House Surgeon and Junior House Physician for six months. Salary £40 per annum in each case, with board, residence, and laundry.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Assistant Physician.

RADNOR COUNTY COUNCIL.—County Medical Officer of Health and County School Medical Officer. Salary £300 per annum.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Male House Physician and House Surgeon for six months. Board, lodging, and washing provided. Also Female House Physician and House Surgeon. Board, lodging, and washing provided. Also Clinical Assistant.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—Resident Medical Officer for six months. Salary at rate of £120 per annum, with board, lodging, and washing. Also House Physician for six months. Salary at rate of £60 per annum, with board, lodging, and washing.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Commissions.

ST. MARYLEBONE ANTI-TUBERCULOSIS DISPENSARY.—Medical Officer. Salary £250 per annum.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Senior Resident Medical Officer, unmarried. Salary at rate of £100 per annum, all found.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon for six months. Salary £80 per annum, with board, residence, and laundry.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

TIVERTON INFIRMARY AND DISPENSARY.—House Surgeon and Dispenser. Salary £80 per annum, all found.

WESTMINSTER GENERAL DISPENSARY, 9, Gerrard-street, Soho, W.—Resident Medical officer. Salary £120 per annum, with rooms, gas, coal, &c.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Act at Shrewsbury, in the county of Salop.

THE Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 37, attached more particularly to High Wycombe, Aylesbury, and Chesham County Courts.

Births, Marriages, and Deaths.

HARRIES-JONES.—On Sept. 29th, at Abington Park-parade, Northampton, the wife of E. H. Harries-Jones, M.D., of a son.

MARRIAGES.

JAMISON—NICHOLLS.—On Oct. 4th, W. Jamison, M.D., Abercynon, Glam., to Edith A. M. Nicholls, daughter of Rev. R. Nicholls, Hornchurch, Essex.

DEATHS.

HILL.—On Sept. 28th, at Bedford-square, London, W.C., Joseph Higham Hill, M.D.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL MATTERS IN CYPRUS.

In his report to the Colonial Office on the Cyprus Blue-book for 1909-10 Sir C. A. King-Harman, K.C.M.G., the High Commissioner, mentions that during the year the medical department of the island sustained a grievous loss in the death of the chief medical officer, Dr. F. C. Heidenstam, C.M.G., who for more than 26 years had ably administered the business of the department. He was succeeded as head of the department by Mr. R. A. Cleveland, the district medical officer of Nicosia. Apart from the prevalence of a somewhat extensive epidemic of cerebro-spinal meningitis (the report goes on to say), the general health of the island during the year was satisfactory and the general sanitary conditions have been good. Meningitis, which had broken out with virulence in 1908, continued fairly prevalent during the spring months of 1909, but as the warmer and drier weather of summer supervened the cases declined till the epidemic practically disappeared. There was a slight recrudescence of the disease in the later months of the year, but there is every indication that the epidemic wave is passing away from Cyprus and that the island will soon be free of a terrible and fatal malady which appears to defy sanitation and treatment alike. No light was thrown on the means of transmission, but it was invariably reported by the medical officers that cold and moisture seemed to be essential to the vitality of the specific microbe, while the opposite conditions of heat and dryness inhibit it. During the year under report the total number of cases throughout the island was 1080, of which 546, or 50·5 per cent., terminated fatally. Malarial fever of the tertian, quartan, and malignant types was prevalent during the year, but to a considerably less extent than in 1908, the total number of cases being only 7450, as against 10,746. A case of Malta, Mediterranean, or undulant fever was discovered during the year. This fever, which in Malta has been traced to the milk of the Maltese goat, has never before been reported in Cyprus, although the Maltese goat is in the island. The central hospital at Nicosia was enlarged during the year by the addition of a new wing for the accommodation of women and children, and a small isolated building with three beds for the reception of destitute cases of consumption marks the commencement of an effort to cope with the advance of that fatal disease. There was no extension of the Rural Medical Service during the year. There are 12 rural stations with a medical officer at each, and a total number of 11,815 patients were treated during the year. The number of inmates at the leper farm at the end of the year was 102. There were 13 admissions and 12 deaths. The chief medical officer reports that the good effects of the system of segregation, compulsory in Cyprus, are beginning to be manifested, and that the disease is on the decline. During the year a trial was commenced of the new treatment by nastin, but nothing very definite has as yet been discovered as to its therapeutic value. The children from the leper farm now living in the Home in Nicosia are 11 in number, and there are three others still in the farms not old enough to be removed. It is interesting to record that no evidence of the disease appears among them, nor was there any serious sickness or mortality. The total number of inmates of the lunatic wards in Nicosia at the close of the year was 54. The new asylum, on an excellent site a mile outside of Nicosia and near the leper farm, was commenced. When completed it will constitute an immense improvement on the existing discreditable arrangements. The absolute mean temperature of the island during 1909-10 was 66·5°, as compared with 65·5° during the previous year. The early summer was unusually hot, and exceptionally high maxima temperature readings were registered in July on Mount Troodos, the absolute maximum being 94°—4° higher than has ever been previously recorded. A minimum reading of 16° of frost was recorded at the asbestos mines, about 4450 feet about sea level. The average rainfall for the whole island was 23·80 inches, a maximum of 64·55 being recorded in the district of Kyrenia, and a minimum of 11·11 in one place in the Nicosia district. The heavy rainfall recorded in the district of Kyrenia is due to the extraordinary rains which fell at Khalevga, near the northern range. This concentration of rain at one place in the northern hills supports the contention that the Kytherea spring, as to the constant supply of which so many theories have been propounded, is really supplied from the rain-water stored in the hills.

THE GRAVE OF DR. JAMES BARRY.

To the Editor of THE LANCET.

SIR,—I wish to inform you that the other day I visited the grave in Kensal Green of that famous female, Dr. James Barry, inspector-general of army hospitals, and found it to be in the same deplorable condition as when I first saw it in 1895. On that occasion, you may remember, a correspondence respecting Barry's wonderful career was carried on for weeks in the columns of THE LANCET, and among other points the subject of her neglected grave was discussed. The sandstone slab, once erect, now lies prone on the grass. The inscription was quite undecipherable until an attendant had swept it clean with a broom and bucket of water! The grave is numbered 19,301 in the Kensal Green Cemetery Record-book, Row 6, Square 67. It lies near a by-path from a main road running parallel with the north wall. As a guide to the exact spot it may be mentioned that at the junction of this narrow path with the roadway stands a pillar erected to the memory of Harriett, the beloved wife of Thomas Rogers, Esq.

It is strange that the grave of so eminent a surgeon as Dr. Barry undeniably was should be neglected all this time. The simple inscription runs thus:—

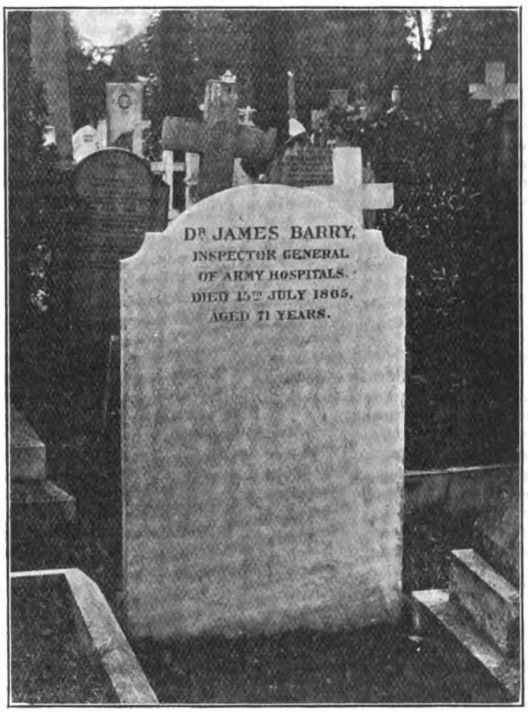
"Dr. James Barry,
Inspector-General of Army Hospitals,
Died 15th July, 1865, aged 71 years."

Moreover, it is significant that although her feminine sex had been made manifest at the inquest (by Dr. J. G. David, Dr. Mackinnon, and Dr. W. A. White, the army surgeons who were deputed by the War Office at her death to hold the inquiry), still the inscription *refers to a man*. The question, too, arises, who set up this slab? Who paid for it? Presumably whoever succeeded to her property. Why has her grave been abandoned, to my knowledge, for 15 years? It could not have been from ignorance of the fact, for her career was widely known and I myself frequently wrote to the papers, and especially to the *Broad Arrow* and THE LANCET, suggesting that a military subscription should be raised, not only to put the grave in order, but to set up some suitable memorial in marble or bronze, recording her virtues and professional attainments. Several medical officers in the services have written to me on the matter; and I fully believe that if a committee were now formed with this object in view it would meet with a ready response.

I have had the grave-stone erected and photographed for the benefit of readers of THE LANCET. I am, Sir, yours faithfully,

E. ROGERS,
Lieutenant-Colonel (Author of "A Modern Sphinx").

London, Sept. 9th, 1910.



FARMER FINED FOR ADULTERATING MILK.

AT the Guildhall police court recently a farmer living at Cheshunt was convicted and fined upon four summonses for selling milk adulterated by the addition of water. The importance of the case, as was explained by Mr. Vickery, who prosecuted on behalf of the Corporation, lay in the fact that small traders are frequently prosecuted for selling adulterated milk to the poor and urge in defence with truth that they have sold the milk as supplied to them, when they are either fined for what is not their fault, or, because they are able to rely upon a warranty of the purity of the milk given by the farmer, are acquitted, when the case goes no farther. The summons in question was, however, due to the action of

Messrs. Gibson Brothers, milk-dealers in New North-road, who had complained of the milk they received, and thus had enabled the authorities to test the adulterated supply at its source, the result being that four samples were taken from different churns on their arrival at the London terminus, which showed the addition of water in the proportions of 8, 12, 14, and 15 per cent. respectively. The suggestion put forward in defence was that the farmer was inexperienced and that his servants had been dishonest. The Alderman, however, was of the opinion that the case was a serious one and inflicted fines, with costs, amounting to a total of £37 14s.

AN INTERVIEW AND AN EXPLANATION.

To the Editor of THE LANCET.

SIR,—In the *Daily News* of last Thursday an interview with me is reported on the effects of systematic fasting. In publishing this a mistake has been made, and I write to express my sincere regret. An article appeared in the *Daily News* some weeks ago describing a fast cure undertaken by the writer. He mentioned certain very interesting facts, and suggested that a committee of medical men should watch a number of selected cases and report. Now I am much interested, having had 18 such cases during the last two and a half years, and so I got in touch with the writer of the article. Last Wednesday a gentleman called on me from the *Daily News* by appointment, and I understood it was to have been a talk preliminary to the formation of this committee of inquiry.

I greatly regret my carelessness in not stating the terms of this interview quite clearly, and I am sure that the fault is entirely mine.

I am, Sir, yours faithfully,

Welbeck-street, W., Oct. 4th, 1910. HECTOR MUNRO.

MEDICAL WOMEN IN INDIA.

A MEETING of the United Kingdom Branch of the Association of Medical Women in India was held on Sept. 28th to meet Miss A. M. Benson, M.D., First Physician of the Cama Hospital, Bombay, in order to hear from her some proposals as to the formation of an organised female medical service for India, and to receive information on the present working conditions of the Dufferin Fund. Mrs. Scharlieb, M.D., presided. The meeting was unanimously of the opinion that the secretary of the Countess of Dufferin's Fund should be a qualified medical woman; that at least one qualified medical woman should have a seat on the central committee of the Fund (at present, except the President, Lady Minto, no woman is on the committee); and that an efficient service of medical women for India should be organised. For the furtherance of these objects it was resolved that the Secretary of State for India and Lady Hardinge (who is the President-Elect of the Dufferin Fund) should be asked to receive some members of the association in order that a brief explanation of the urgency of the need in India for an efficiently organised service of medical women may be set before them.

A MODIFICATION IN THE METROPOLITAN WATER-RATE, AND A HINT TO LANDLORDS.

To the Editor of THE LANCET.

SIR,—It is important for your readers to know that the London Water Board is now levying a special rate on dentists; this has been "sprung" on householders without any notice. It dates from April 1st, and the first demand is for the two quarters extending from that date to Sept. 30th. The Board declines to recover the rate from dental surgeons who are sub-tenants; and it will therefore be necessary in letting consulting-rooms to make provision for this contingency, because the amount charged a householder may suddenly rise to an extent which was not anticipated. At present it varies from £1 to £3 per annum per dental surgery; but this is likely to be further increased. Being specially a rate levied on every dentist, it would be fair that a clause be inserted in every agreement that this rate, whatever it be, should be refunded to the householder by the sub-tenant. That I should do in my own case were I having an agreement drawn up *re* a consulting-room.

I am, Sir, yours faithfully,

Sept. 29th, 1910. WEST-END.

WANTED, SUGGESTIONS FOR TREATMENT.

To the Editor of THE LANCET.

SIR,—Can any of your readers advise me as to treatment for the following case? A female, aged 28 years, has cystitis due to B. coli which has lasted some months; the urine has no albumin, but a few pus cells have been present from time to time. She has been treated with helmitol and urotropin, and for about a month the B. coli disappeared, but have since returned. The uterine functions are normal, and there is no evidence of renal calculus and no calculus could be seen with the X rays. The uterus and appendages are normal. She is losing weight and a different form of treatment is imperative.

I am, Sir, yours faithfully,

A. BRODIE CREAK, M.R.C.S. Eng.

Balholm, King's Heath, Birmingham, Sept. 30th, 1910.

S.B., M.R.C.S., &c.—The suggestion of our correspondent that the digested bacilli of swallowed sputum in phthisis might possibly form in the blood of the infected individual an antibody which would increase his resisting power and bring about a cure of the disease is a view of the possibilities of vaccine therapy which is both novel and comforting.

M.B., B.C.—The insurance is a protection of the employer against the claims of the employed, and has nothing to do with the matter. The tradesman who summoned our correspondent appears to us to be liable for the charges, and we believe that this view would be supported by most county court judges.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Oct. 10th–15th (London).—Town Planning Conference.
" 13th–15th (Paris).—Eleventh French Congress of Medicine.
" 16th–22nd (Barcelona).—First International Spanish Congress of Tuberculosis.
Nov. 7th–12th (Cape Town).—Twelfth South African Medical Congress (1910).

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: Albert Carless, James Galloway): at 8.30 P.M.

Dr. George Oliver: Two New Methods (Auscultatory and Visual) of Reading Arterial Blood-pressure.
Mr. L. V. Cargill: Acromegaly associated with Tumour (Cystic?) of Pituitary Body.
Mr. Douglas Drew: (1) Rupture of Cord of the Brachial Plexus; (2) Separation of the Lower Epiphysis of the Humerus with Displacement; (3) Tumour of the Rectus Abdominis in a Child.
Dr. H. D. Rolleston: Multiple Fatty Tumours (? Adiposis Dolorosa).
Mr. Albert Carless: Early "Dercum's Disease."
And other cases.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., General Meeting. 8.30 P.M., Opening Address:—Mr. C. Symonds (In-coming President): The Treatment of Chronic Abscess of Bone by Means of Metal Drains (illustrated by patients, preparations, and radiograms). A Discussion, to be opened by Sir Watson Cheyne and Mr. A. E. Barker, will follow.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Dr. H. D. Rolleston: Acute Arthritis of Doubtful Origin.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22 Chenies-street, W.C.

MONDAY.—4 P.M., Mr. J. E. R. McDonagh: Clinique (Skin). 5.15 P.M. Lecture:—Dr. N. Tirard: Some Cases of Diabetes.
TUESDAY.—4 P.M., Dr. E. Wynter: Clinique (Medical). 5.15 P.M. Lecture:—Dr. G. Pernet: Syphilitic Headaches.
WEDNESDAY.—4 P.M., Mr. A. P. Gould: Clinique (Surgical). 5.15 P.M. Lecture:—Mr. W. Stuart-Low: The Nasal and Operative Treatment of Asthma.
THURSDAY.—4 P.M., Dr. L. Guthrie: Clinique (Medical). 5.15 P.M. Lecture:—Dr. F. J. McCann: On Some Common Mistakes in the Diagnosis of Cancer of the Uterus.
FRIDAY.—4 P.M., Dr. D. Grant: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M. Opening Address.—Dr. D. W. C. Hood, C.V.O.: Specialism in Medicine.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operation. 11.30 A.M.: Demonstration in Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical (with cases).
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M. Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine (Lecture I.).
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.39 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M. Lecture:—Mr. Baldwin: Practical Surgery (Lecture I.).

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical (with cases).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Batten: Cerebral Disease.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Batten: Tabes Dorsalis.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Mr. C. Nourse: External and Middle Ear.

T. JOHN'S HOSPITAL FOR DISEASES OF THE CHEST, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Erythema.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. E. S. Bishop: Appendicitis. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (12th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (13th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (15th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

K.—Messrs. R. A. Knight and Co., Lond.; Dr. Knight, Portobello; Messrs. Kutnow and Co., Lond.; King's College, Lond., Principal and Staff of; Dr. M. Koch, Horley.

L.—Mr. H. K. Lewis, Lond.; Messrs. E. and S. Livingstone, Edinburgh; Mr. Stuart-Low, Lond.; Local Government Board, Lond., Secretary of; Liverpool Stanley Hospital, Hon. Secretary of; Mr. R. T. Lang, Lond.; Mr. C. Lillingston, Mundesley-on-Sea; Dr. T. D. Lister, Lond.; Mr. B. C. A. Leeper, Maidstone; *London University Gazette*, Publisher of; London Hospital Medical College; Mr. E. Leitz, Lond.; H.R.H. Princess Louise, Lond.; *Londoner Zeitung* "*Hermann*," Editor of.

M.—Dr. J. W. Milne, Aberdeen; Messrs. Matthews, Matthews, and Goodman, Lond.; Mr. W. Martindale, Lond.; Dr. George A. Mason, Lond.; M.B., F.R.C.S.; Dr. J. C. McWalter, Dublin; Dr. Dan Mackenzie, Lond.; Medical Society of London; Mr. John Murray, Lond.; Dr. A. Morison, Lond.; Messrs. D. Macfarlane and Co., Paisley; Maltine Manufacturing Co., Lond.; Dr. J. Keogh Murphy, Lond.; Dr. F. W. Mott, Lond.; Messrs. C. Mitchell and Co., Lond.; Mission to Lepers in India and the East, Lond., Organising Secretary of; Manchester Royal Infirmary, Secretary of; Meerut Medical Association, Secretary of; Professor Howard Marsh, Cambridge; Middlesex Hospital Medical School, Lond., Chairman and Council of.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; Newcastle-on-Tyne City Asylum, Clerk to the; Mr. Walter S. Nowell, Lond.; Nottingham Mothers' and Babies' Welcome, Hon. Secretary of; National Food Reform Association, Lond.; National Hospital for the Paralysed and Epileptic, Lond.

O.—Professor W. Osler, Oxford; Messrs. Osborne Peacock Co., Manchester; Owner, Pembridge-square.

P.—Messrs. Peacock and Hadley, Lond.; Dr. L. Phillips, Surbiton; Dr. E. T. Pritchard, Lond.; Messrs. Pennington, Manchester; Mr. J. E. Purvis, Cambridge; Miss E. Page, Harold Wood; Dr. Constant Ponder, Cambridge; *Pathé's Animated Gazette*, Lond., Editor of; Messrs. George Pulman and Sons, Lond.; Pearson's Antiseptic Co., Lond.; Dr. G. Parker, Clifton; Pharmaceutical Society of Great Britain, Lond., Secretary of.

R.—Mr. D. Olson Riddel, Oyne; Dr. Frank Wade Robertson, New York; Royal Halifax Infirmary, Secretary of; Rotherham Hospital, Secretary of; The J. D. Riedel Co., Lond.; Royal Society of Medicine, Lond., Secretary of; Royal Devon and Exeter Hospital, Secretary of; Royal College of Physicians, Lond., President and Fellows of; Royal Institute of Oil Painters, Lond., President and Council of; Royal Surrey County Hospital, Guildford, Hon. Secretary of; Messrs. Rebman, Lond.; Messrs. Reynolds and Branson, Leeds.

S.—Scholastic, Clerical, &c., Association, Lond.; Secretary, Finsbury-square; Dr. T. H. Suffern, Okigwi; Southport Infirmary, Secretary of; Messrs. W. H. Smith and Son, Clifton; St. Mary's Hospital for Women and Children, Lond., Secretary of; Messrs. Spiers and Pond, Lond.; Mr. Herbert Sieveking, Lond.; Miss Solly, Southampton; Mrs. E. M. Slater, Lond.; Mr. Albert Sheppard, Lond.; Mr. Spencer, Aberystwyth; Messrs. C. G. Spencer and Sons, Lond.; Mr. N. I. Spriggs, Leicester; Scarborough Hospital, Hon. Secretary of; St. Andrew's Hospital, Northampton, Clerk to the; Messrs. W. B. Saunders Co., Lond.; Sheffield Royal Hospital, Secretary of; Dr. M. T. Smith, Wallace, U. S. A.; Svenska Nationalföreningen mot Tuberkulos, Stockholm, Secretary-General of; Messrs. R. Sumner and Co., Liverpool.

T.—Dr. J. Raglan Thomas, Exeter; Dr. J. C. Thresh, Chelmsford; Messrs. C. Tayler and Co., Lond.; Right Hon. Lord Tenterden, Lond.; Dr. E. Tiessen, Berlin; Messrs. R. Tidey and Sons, Lond.; Mr. Tainton, Chalford; Dr. H. Tod, Lond.; Tiverton Infirmary, Hon. Secretary of.

U.—Dr. Henry S. Upson, Cleveland; Union Reclame, Berne; University College, Lond., Provost of; University of London, Secretary to the Senate of.

V.—Messrs. J. W. Vickers and Co., Lond.; *Votes for Women*, Lond., Editors of.

W.—Mr. J. Walker Wood, Lond.; Messrs. John Weiss and Son, Lond.; Mr. F. L. Wilson, Lond.; Mr. H. de C. Woodcock, Leeds; Dr. J. C. Wilson, Philadelphia; West London Post-Graduate College, Dean of; W. W.; Messrs. J. Wright and Sons, Bristol; Wolverhampton General Hospital, Secretary of; Westminster General Dispensary, Lond., Secretary of; Mr. A. P. Walters, Exeter; West Riding A. B. C. Publishing Co., Leeds; Dr. J. J. Wallace, Edinburgh; Professor D. A. Welsh, Sydney; West Riding of the County of York, County Medical Officer of Health of; Westminster Hospital Medical School, Secretary of; West-End; Mr. Walter G. Walford, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. E. Arnold, Lond.; A. R.; Apollinaris Co., Lond.; A. M. I.; Miss Atthill, Monkstown Castle; A. E. H.; A. J. L.; A. T. G.; Dr. W. H. W. Atlee, Eton; Messrs. Armour and Co., Lond.; Rev. W. Atthill, Boscombe; Dr. J. F. Allen, Pietermaritzburg; A. M.; A. P. B. E.

B.—Mr. F. H. Bellringer, Windsor; Mr. H. Bennett, Builth Wells; Mr. A. Blair, Newport, Monmouthshire; Dr. G. A. Brogden, Oadby; Bedford Motors, Lond.; Benger's Food, Manchester; Mr. C. Birchall, Liverpool; B. J. B.; Dr. A. Brugiadino, Montecarollo; Bristol Myers Co., Brooklyn; Mr. M. F. Banerji, Bagnapari; *Barrow Guardian* Office, Manager of.

C.—Dr. C. Clarke, Lond.; C. E. F.; Mr. W. E. Coleman, Wednesbury; Dr. G. Cowan, Thetford; C. B.; Messrs. E. Cook and Co., Lond.; Mr. A. K. A. Caesar, Chilham; Messrs. Crossley and Co., Lond.; Messrs. T. Christy and Co., Lond.; Dr. E. Coles, Oxford; Mr. C. E. Cowen, Cala; C. M.; C. E. B.

Y.—Messrs. Douglas Young and Co., Lond.

An Address
ON
THE EDUCATION OF THE STUDENT OF MEDICINE.

Delivered at the Opening of the Winter Session (1910–11) in the Medical Department of the University of Leeds,

BY F. HOWARD MARSH, M.A., M.C. CANTAB., F.R.C.S. ENG.,

MASTER OF DOWNING COLLEGE, AND PROFESSOR OF SURGERY IN THE UNIVERSITY OF CAMBRIDGE.

MR. VICE-CHANCELLOR, LADIES, AND GENTLEMEN,—I am aware that I am standing in a position of much responsibility. But when your Council did me the honour of inviting me to present the prizes and give the introductory address to-day I felt that I ought not to decline. Duty must be done. But there was a consideration that at once presented itself to my mind which made the task I was undertaking thoroughly congenial. I remembered that I should be speaking in Leeds, where one of the most interesting and worthy of the men whose names stand clearly inscribed on the pages of the history of our profession lived and worked, and where his successors have made the medical department of the University of Leeds a foremost centre for the cultivation of the science and art of surgery.

WILLIAM HEY.

The seniors among you must be familiar with all, and with much more than I can tell about William Hey, but in speaking to the young pilgrim warriors who set out to-day, I wish, as one who has borne the burden and heat of the journey, to tell what I seem to have learned, and the conclusions which I have formed touching those things about which, when the time for a retrospect shall come, there may be as much as possible to remember with satisfaction, and as little as possible to regret. And for this purpose the life and personality of William Hey furnish me with a most suitable text. Even advanced students know Hey only as the inventor of a saw which is never used, and an operation which is never performed. Let me try to say more than this about him.

Hey was one of three brothers, each of whom attained high distinction. John, the eldest, born 1734, came up to Cambridge, was eighth wrangler, and, later, a Fellow and Tutor at Sidney-Sussex College. In 1780 he was elected as the first Norrisian Professor of Divinity, and William Pitt attended his lectures on morality—a training of much value to a politician, as we shall all no doubt agree, not only in Pitt's time but at the present day. John became a Doctor of Divinity, and wrote several treatises, which went through three editions. To this day he is high on the list of Cambridge worthies.

Richard was also a Cambridge man. He was third wrangler and won the Chancellor's medal in mathematics in 1768, became a Fellow and Tutor at Magdalene, and Esquire Bedell, and took the degree of LL.D. He wrote three dissertations—on the pernicious effects of gaming, on duelling, and on suicide, for each of which he received £50 through the University from an anonymous donor. These essays, after the manner of the time, were compositions in which the subjects were elaborately worked out under a number of heads, and from every point of view. They display much ingenuity and close argument, and are written in a clear, copious, and robust style. He shows not only that these things are wrong in every aspect in which they can be regarded, but that they are foolish and indeed contemptible. It seems certain that no one who reads them with an open mind will ever game, fight a duel, or commit suicide again. He also wrote a novel. Richard Hey was the kind of man one would have much liked to know. His conversation must have been interesting and entertaining. He attained the ripe age of 91.

Your William Hey, born in 1736, had from the first a single eye to his profession, for he lost his right eye when he was four years old. This must have been a heavy handicap, but the calamity was diminished by the circumstance that it occurred in infancy, so that the eye which was left had time to prepare itself for its heavy responsibilities. This is not the occasion for alluding to Hey's individual contributions to surgery: their value is well known in Leeds and widely recognised elsewhere. But of the man himself, I should like to offer some estimate for which our business to-day affords ample justification. After having been a student at St. George's Hospital, he came at once to Leeds, and was soon engaged in active practice. He was brought in contact with that extraordinary man, Joseph Priestley, the discoverer of oxygen, who had become in 1767 Presbyterian minister of Mill Hill Chapel in your town, and through him he was elected a Fellow of the Royal Society in 1775. In 1767 Hey was prime mover in founding the Leeds Infirmary, where afterwards he was senior surgeon for 39 years—from 1773 to 1812. He was twice Mayor of Leeds. In this office he so vigorously denounced vice and profanity that the populace burnt him in effigy, and threatened him with personal violence. He was a skilled musician, and for some time President of the Leeds Literary and Philosophical Society. He was a sound patriot, for he had 11 children. He died at the age of 83, in 1819. His works published in 1810 are written in language which is so clear, direct, graphic, and vigorous, that to this day it is a genuine pleasure to read pure English turned to so good an account. He owed the respect in which he was held for so many years, not only to his ability and culture—these indeed never suffice—but to his honourable and high character. He may be taken as an example of the man whom Horace, in one of the gems of classic literature, has pictured in the lines which he addressed to Aristius Fuscus, and which every young man would do well to bear in mind:—

> "Integer vitæ scelerisque purus
> Non eget Mauris jaculis, neque arcu
> Nec venenatis gravida sagittis
> Fusce, pharetra."

Of these lines Sharp has given the following translation:—"Fuscus, he who hath integrity of life and is free from wickedness needs not Moorish javelins, nor bow, nor a quiver laden with poisoned arrows." For (he adds) in the Sabine wood a wolf fled me, though unarmed.

We must without hesitation assign to Hey a place on the list of those who have left great names in English surgery, beginning with Richard Wiseman, and coming down to the most renowned amongst them all, Lord Lister. Reckoning that a surgeon is at his prime at the age of 50, we may, I think, take the following names and dates as correct: Wiseman 1672, Cheselden 1738, Pott 1764, Hunter 1778, Hey 1786, Astley Cooper 1818, Lawrence 1833, Syme 1849, Paget 1864, Lister 1877. To be one of ten worthies distributed over a period of 205 years is assuredly no mean distinction. With Hey before him no Leeds man can, if he fails or goes astray, plead the want of a high ideal that he might have followed.

It must, I think, be interesting at the present day to recall for a moment who our predecessors have been, and the conditions under which they worked. What were the qualities which brought these ten men, each in his generation, into the first place, and set them apart—*longo intervallo*—from the rest who, though good men in their day, have now sunk deep into the forest shade?

First of all they were men of originality and enterprise. It could not be said of them that—

> "With packhorse constancy they kept the road
> True to the jingling of their leaders' bells."

They were leaders, not followers. They were genuine students, who aimed at advancing and improving the surgery of their day without the low ambition of personal notoriety, or over much financial success. Wiseman, Astley Cooper, and Lawrence were the handsome men of the group; Cheselden, Hey, and Lawrence probably the best read and most accomplished. Others were from the first so absorbed in the work immediately before them that they had no time to wander in the shady groves of the *Academia vetus* and listen to the teaching of Plato. They picked up their own sterling philosophy, and acquired not sham but real culture as they went along. Many a fop and many a prig in philosophy or the fine arts would have found his true level with, for instance, Sir James Paget, whose society was sought by the most cultured people of his day. Hunter had no accomplishments, nor did he desire them; at least we know, from what occurred at Oxford, that an academic career had no attractions for him.

It is often asked how the early surgeons could have

operated without anæsthetics. That they did so is claimed by the ignorant and uncharitable as a proof that they were callous and brutal. It is easy to prefer such charges against the pioneers of what surgery has now become, or for the anti-vivisectionists of our time to bring accusations against such benefactors of mankind as Paget and Lister. The truth is they know not what they say. History will assign to them their proper place when the day of reckoning comes. But to those who, in good faith and Christian charity, ask how these things could be done the answer is that the old surgeons were impelled by what they witnessed of the sufferings caused by disease—and of which we of to-day can have only a faint conception—to find, if possible, some means of relief; that they attained in many instances a reassuring and encouraging measure of success; and that they were well aware that they were laying stepping-stones which their happier successors should tread.

William Hey, junior, was, like his father, a man of ability and culture. He will be remembered chiefly for his treatise on puerperal fever. Of him and of the able and conscientious men who were associated with him in the study of this dread disease, which played such havoc in Leeds and its neighbourhood in 1809 to 1812, we can only say that the time was not yet. They could only study results, and all their efforts to understand the nature of the disease were null and void, and their best attempts at treatment can now only affright, and fill us with distress. The case is but another example of the truth that great discoveries—that is, excursions into the hitherto unknown—must wait till the agency through which alone they become possible has been provided. Without wings, however keen the gaze, the point-to-point flight cannot be made. It was so with William Hey, junior, and his colleagues. The main questions around which their discussion circled were whether the disease was, or was not, infective; then, if it was, how did it arise. The search was close and earnest, but it was foredoomed to failure. Something was wanting before the riddle could be solved. How often on like occasions has that something been a contribution from one of the other sciences—in astronomy, a telescope or a photographic plate; in pathology, a microscope or an X ray picture; in physiology, an electric current or a chemical agent such as chloroform? In the instance before us matters had to wait for another 60 years, until the microscope was so far perfected as to furnish the means for new methods of research, and to render Pasteur's investigations possible. After that Lister could follow the same lines of close observation and reflection which Hey and his contemporaries had pursued, and was able to succeed where they had failed, and so the tremendous event, the discovery of the nature of infection in surgical practice, was attained.

Does not all this remind us that there can be no partition walls in the field of intellectual progress; that all the sciences are but parts of one stupendous whole—

> "Children of divers kind
> We, sucking on earth's natural bosom, find,
> Many for many virtues excellent.
> None but for some, and yet all different."

Many dialects, yet a common language. May not the devotees of science well exclaim with the Galileans, How hear we every man in our tongue wherein we were born? Parthians and Medes and Elamites—and the rest—we do hear them speak in our own tongues the wonderful works of God. Are we not, indeed, come we whence we may, pilgrims travelling to the same shrine, where the cry is still, as it was with Goethe—"Light, more light!" and where we hear, ever in clearer and clearer tones, the responsive mandate, "Let there *be* Light."

PRESENT POSITION OF MEDICAL EDUCATION.

I now turn to the present position of medical education, and I think that even a cursory examination of this supremely important question must give rise to serious misgivings. As medicine has now become a department of biology, its pursuit necessarily demands a sound acquaintance with the broad principles of those departments of biological science with which it is intimately connected, which are, in fact, the foundations on which it rests—chemistry, anatomy, physiology, and pathology. Here are four sciences each of which has a horizon to which no limit can be assigned, and which is constantly undergoing expansion. Every year, to their honour be it said, the pioneers of all of these sciences are forging ahead and initiating new methods of investigation, so that the work is always increasing in novelty, complexity, and quantity. Moreover, things are at first seen, as it were, through a glass darkly, and new facts cannot at once have their proper places allotted to them, or be brought into harmonious relation with their environment. They are therefore difficult to teach, and infinitely more difficult to learn. In other words, in the borderland between the former and the new, the material in hand is plastic and has not as yet had time to crystallise into its ultimate form. Now, the difficulty which the student experiences is to keep pace with his subjects. He does not doubt that lecturers are master hands, but he finds that the material dealt with covers so much ground, and is, as I have said, so novel and complex, that he is conscious that he is being left behind. It seems to him that his teachers are like the giants of old and in their attempts to scale the heavens are heaping Ossa on Pelion, and inadvertently crushing his prostrate form beneath the superincumbent weight. And may it not sometimes be that recent advances are so seductive to the teacher that they tempt him to introduce them to his class, with the result that he does not dwell with sufficient emphasis and repetition on the more prosaic principles of his subject, albeit they are all that the embryonic student can fully grasp or even partially understand. A class which has passed through one of these preliminary courses may be divided into the abler and the average man. The former in many instances has acquired an amount of knowledge which does him infinite credit. But it is knowledge of a particular kind. It is almost all on the surface. It has not had time to eat its way in and become deep-set. It is very largely a question of mere memory. Take such a man off the line along which he has been rapidly conducted, and turn the subject round, and present it in a fresh aspect, and he is soon beyond his depth. It becomes obvious that though he has remembered much the knowledge has not become his own; he has not, indeed, had leisure in which to read, mark, learn, and inwardly digest it. He has not, in the words of Richard Wiseman, "been able to set some time apart for reflection upon his labours."

With the average man the whole business has from the first been hopeless. His mind is not a sensitive photograph plate on which a short exposure, however good the lens, will secure a clear and abiding picture. He has been outpaced, and, with all sympathy be it said, he has been spending many an hour *strenue nihil agendo*—in strenuously doing nothing. All along he has been conscious of a mental surfeit, and as soon as he has happily got through his examination he turns from his depressing task with a feeling of profound relief, and discards his subject without even the forms of regret.

I am anxious to avoid anything like exaggeration, and particularly to keep, with a good margin, clear of even the appearance of criticising teachers whose only fault is that they cannot achieve the impossible. I desire only to raise the question, once again, whether some modification of the present system is not urgently required.

I know that a large number of the ablest teachers of the day are anxious that a satisfactory solution should be found. The problem is how to cut the garment according to the cloth—how to arrange the work so that the curriculum of the student of medicine shall lead to satisfactory results. We have to remember, *Ars longa, vita brevis*. Professor E. H. Starling (and where can we find a higher authority?) has put the matter in a nut-shell (let the medley of metaphors be forgiven) when he says you cannot put a quart of fluid into a pint pot.

The difficulty which we have to face is of no recent origin. On the contrary, it is one of the oldest in the whole field of education. Confessing that no one can learn everything, it becomes a question of *selection* and of determining in any given case what is really *ad hoc*, what is the particular knowledge which the student requires, and how much of this he can be taught in the circumstances in which he is placed.

But this is not the only matter before us. We have to consider the result of the present system, not merely in reference to what the student has learned, and will retain in a serviceable form for future use, but what kind of mental training he has been passing through, and what effect his work has had on his mental evolution. Is not this a matter of supreme importance? Is there any calling which demands a wider diversity of well-matured mental qualities,

a more many-sided education in the true sense of the word, than ours? How can a profession which has its foundations laid in the four sciences which I have mentioned, and which constantly avails itself of them and uses their methods, be adequately followed by anyone who has not had a scientific education, whose higher mental faculties have not been judiciously developed and cultivated? As practitioners of medicine we are frequently called upon to deal with problems which are in a high degree complex, in which the underlying facts are numerous, widely diverse, and often, as it seems, contradictory, while our knowledge is, as we are often painfully aware, rudimentary, so that we are working in dim twilight, or even wholly in the dark. Moreover, however unconscious or forgetful of it we may be, we are invariably face to face with facts which always claim to say the last word. In the practice of the law facts are as clay in the hands of the potter; in theology facts and dogmas are often convertible terms; but with the surgeon, as with the engineer, facts are stubborn things. Let the engineer build too flimsy a bridge, or the surgeon overlook a fracture or an appendicitis, and the fact will avenge itself. In both cases alike the penalty will have to be paid in coin of the surgeon's regret and of the patient's injury. If all this is true, does not the training of the student of medicine claim a foremost place? Mere information is, so to say, but raw material and of little value to the student unless he can manufacture it for his own use. But how can he do this when he is constantly in active pursuit, when, to put it in another way, he is being constantly overfed with material which he cannot assimilate? May not his condition be fitly compared to a round-celled sarcoma in which only disorderly growth, but no development is taking place? Instead of developing his powers of observation, which in most of us, when we compare them with those of a portrait painter, a naturalist, a Red Indian, or many of the birds and lower animals, are conspicuously rudimentary and defective; instead of forming the habit of thinking closely over what he has observed; instead of learning to collect, analyse, and arrange evidence, and acquire a judicial habit of mind, we see him leaving his higher faculties in abeyance and surcharging his memory with what are to him mere crude and amorphous details—*rudis indigestaque moles*—with the result that in hours of depression he emphatically endorses the statement of the Preacher that "much study is a weariness of the flesh."

IMPORTANCE OF ESSENTIALS.

All this forces itself on my mind alike at examinations and in class-teaching in surgery. I find that men who are quite obviously intelligent and serious students show an altogether deficient acquaintance with, for instance, the essentials of surgical anatomy. They evince little sense of proportion and seem to have paid as much attention to the interlacement of small nerves in the side of the neck as to the landmarks in the middle line; to the details of the origin and insertion of the abdominal muscles as to the anatomy of inguinal hernia; to the anastomosis of arteries around the knee as to the relative position of the important structures in the popliteal space, or the mechanism of the knee-joint, with the result that, having tried to learn everything, they have mastered hardly anything—anise and cumin seem in their eyes to be of very much the same value as the weightier matters of the law. Was not Sir William Turner the foremost anatomical teacher of his day because he drove home the principles of his subject in carefully selected examples, and because he kept to essentials and largely eschewed detail? His idea seemed to be that, as it was impossible to teach the whole of his subject (and that if he could a great deal would be entirely useless to medical students), his proper course was to take what was essential and sternly leave the rest. Under this regimen his pupils had time to assimilate what he taught them, and the result has been that many men who passed through his hands have in their turn become distinguished teachers of the subject. I have heard that Lord Leighton, when a young man, on returning from Italy, brought ten copies of pictures which he had made in a fortnight. Asked how he could possibly have done so much in the time, he replied that he had thoroughly learned the first principles of painting.

In alluding to this question I cannot refrain from saying that the present rate of rejections, taking into account the, to my mind, unquestionable fact that the students of to-day stand at a high level of intelligence and industry, is very notable. The rejections in anatomy and physiology at the conjoint examinations of the two Royal Colleges in the last five years have been between 39 and 47 per cent.; last year they were 45 per cent.; while those in surgery were nearly 50 per cent. Ought we not to inquire how these figures can be explained? How is it that little more than half the number of students who present themselves have reached the standard of a pass examination? I was, myself, for some years an examiner in anatomy and in surgery for the Royal College of Surgeons of England, and I am convinced that the standard is not at all too high. I venture to say that the high rate of rejections is, at least in some degree, due to the circumstance that men have been from the first struggling under the incubus of an overloaded curriculum: and I know I am merely agreeing with many prominent leaders that if we could throw out some ballast the ship would make better ocean way. Could there be some adjustment, the teaching of the preliminary subjects would become in the highest degree valuable to the student of medicine; for he would not only have had the foundations of his work laid on a broad and lasting foundation, but he would have been made, in a real sense, a student of science. The difficulty has for some time attracted general and earnest attention, and the authorities concerned have taken the matter long in hand. It is with this movement that, in all humility, I desire to associate myself. The time seems to have come for taking the bull by the horns, and considering where the line should be drawn, by general consent—is this really beyond the wit of man to achieve?—between that which is of primary and that which is of secondary or even of third-rate importance, and then for concentrating the attention of the student on the former only. Does not every great pleader, in addressing a jury, dwell on chief considerations, and by frequent, or as it may seem tiresome, repetition drive home the main points of his case instead of watering them down, and washing out their colour by mixing them up with too many details? Does he not know that his success lies, not in an elaborate argument, in which, like Burke, he goes on refining, but in his being able to make the jury see clearly three or four points which, as he strives to convince them, entitle him to a verdict in his client's favour?

PROPOSED CONFERENCE.

Might not a medical education conference be held at which all who are interested should be represented. No one can be more conscious of the difficulties of the situation than myself. Yet I believe there is good ground for hoping that great advantage might be secured if a conference could be held. The objects of the conference would be to consider the question of the education of the student of medicine as a whole; to recognise limitations necessarily imposed by the period beyond which the curriculum cannot be extended; to determine the part which each preliminary subject should take; and to agree as to what is essential and what can be dispensed with without real loss, or even with advantage.

There are some considerations which I think would have a weighty influence in promoting the success of such a conference:—

1. The mere meeting together of the representatives of the general body of teachers would in itself emphasise the fact that the object in which all alike are engaged is, not the training of specialists in the individual sciences concerned, but the education of students of medicine.

2. As medicine has now become a department of biology, and as the responsibility of its leaders to the community is yearly increasing, are they not justified in making, are they not indeed constrained to make, an earnest appeal to specialists in other subjects for their generous assistance, seeing that without their coöperation the adequate education of medical students is no longer possible?

3. Each teacher, subject only to the limitations imposed by the object in view—medical education—would be absolutely independent and in every sense unfettered.

4. Each would enjoy the satisfaction of knowing that he could make his teaching thorough, and turn out students who had acquired not merely an evanescent smattering but a sound and permanent grip of the principles of their subject. To take anatomy, the subject on which, as a former teacher, I may venture to speak, I cannot but believe that professors in the universities, and lecturers in the medical schools, would find this amended programme a

great relief. Not being medical men they would welcome some definite information as to the lines on which their teaching of the subject would be most valuable, and as to the areas which would furnish the best illustrations for medical purposes of the principles they desired to enforce.

5. Demonstrators of anatomy would have constant opportunities for going beyond mere tedious anatomical facts to their meaning as to function and their bearing on medicine and surgery. The value of such teaching would be at once apparent when the student began his clinical work, and when a sound knowledge of anatomy is essential. To speak plainly, is it not a farce to discuss femoral hernia, flat foot, or the deformity of the knee-joint in tuberculous disease with a student who has never thoroughly known or who has forgotten his anatomy?

TEACHING OF SURGERY.

As to surgery—I will not venture a word as to medicine—is the teaching of this subject in all instances well organised and sufficiently methodical? My feeling is that this is not the case. Surgery, as I have already said, makes special demands on the powers of observation, a trained eye, a delicate touch of hand, skilful manipulation, a familiarity with the use of instruments and appliances, and the technicalities of aseptics, while some straight hints to the student as to his duties and responsibilities when he becomes a clinical clerk or dresser are urgently required. Moreover, is it not advisable that pains should be taken to fully instruct the beginner in the principles which underlie the collection and use of evidence, to emphasise the difference between the forms of evidence—between the direct and the circumstantial—and to show in what cases the one or the other, or a combination of the two, must be depended on, and what difficulties have to be met, and what pitfalls avoided? Most men are naturally very unobservant. It is startling to see what they can overlook. How true it is that the eye can see only what the eye brings the means of seeing; how real is the danger that he who is untrained to observe critically, and discriminate accurately, will see what he is looking for. Before he begins the study of medicine and surgery, should not the student pass through a preliminary course in which the matters I have briefly alluded to are thoroughly and systematically taught? Would he not keenly appreciate such instruction, and would he not find it of inestimable value in the out-patient rooms, the wards, and the operating theatre? As all these things are necessary ought the student to be left to pick them up haphazard? Would such a happy-go-lucky proceeding be allowed in the instance of a lieutenant on board a cruiser, or an apprentice at Elswick? Yet are not such cases to all practical purposes the same?

I pass over the out-patient room and the special departments, for I believe they are, in all important medical schools, admirably conducted, and that they contribute, in a degree that can hardly be exaggerated, to the education of the student.

In the wards, though there are many exceptions, teaching could with great advantage be somewhat remodelled. Every hospital ward teems with material for clinical teaching. Every case serves as a text. And it is in the wards that the student should gain a very large share of his professional education. The surgeon in charge—and the more eminent he is the more will it be the case—cannot possibly give much time to systematic teaching. Would not three hours a week be an outside figure? To provide him with thorough and ample clinical instruction should not the student, fresh from the preliminary class, pass into the hands of a ward tutor? This appointment has been made already in some hospitals. The ward tutor is a junior teacher. He has a class limited to ten. These he instructs in a suitable number of cases, in note taking, surgical anatomy, symptoms, methods of examination, special appliances, and so forth. His aim is to be thorough, and to work out the cases he selects with deliberation and completeness. Such work as this would not only interest but educate a man, while there can be no doubt that it would be highly valued by every intelligent student.

The work of the tutor when properly and loyally performed would not interfere with cases in which the visiting surgeon was interested, or with his authority, to the wards. Such cases as he desired would be left entirely alone. The tutor would take only cases in which the surgeon, for teaching purposes, did not concern himself; nor would this be any drawback, for the simplest cases, after all, are the most suitable for the instruction of beginners.

A special word to those who from to-day are to have the University of Leeds for their *Alma Mater*. To those who have won the prizes which it has been my pleasant office to present, let me say this. You must recollect that there has been a "proxime accessit" close on your heels. You have won your first obstacle race, but you will find many more in front of you as the years roll on, and if you are still to win you must keep in mind the fable about the hare and the tortoise. Those who have not won this time no doubt mean to do so on the next occasion. For them the fable must be Bruce and the Spider. But let both sides note that prizemen often fail, and that men who do not get prizes often succeed, later on. All must remember that duty is the stern daughter of the voice of God, and that the best asset for any man is a high and honourable character.

INDUSTRIAL TUBERCULOSIS.[1]

BY T. D. LISTER, M.D. LOND., F.R.C.S. ENG.,

PHYSICIAN TO THE MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, HAMPSTEAD; VICE-PRESIDENT OF THE LIFE ASSURANCE MEDICAL OFFICERS' ASSOCIATION.

TUBERCULOSIS is a disease brought about by infection among those predisposed to it, whether such predisposition arises from inheritance, environment, or pre-existing disease. It does not attack the robust unless the dose of infection or its virulence is excessive. Wealth protects against consumption by providing the food, clothing, and leisure, and especially the knowledge, housing, and environment which render the ubiquitous bacillus comparatively impotent. Poverty, overcrowding, fatigue, malnutrition of every kind, with ignorance, indifference, and other attendant evils, physical, social, and moral, are its universal allies.

The industrial classes suffer from consumption at least twice as heavily as the leisured classes, and in many occupations the penalty paid in phthisis mortality is from five to ten times that of the phthisis mortality falling upon those who do not toil. The conditions under which many industries are carried on, and in which a large proportion of workers live, are therefore powerful agents predisposing to tuberculosis.

The considerations which form the bulk of this paper are based upon a study of the mortality of phthisis in various groups of the population of England and Wales. In all studies of statistics which deal with the occupational mortality from phthisis, it must always be remembered that the naturally weak will tend to leave or to avoid those occupations which make demands upon great strength or activity. They tend also to drift into the ranks of those engaged in casual and light labour. Alcohol, no doubt, is also responsible for recruiting these ranks, as well as being a prevalent cause of death in many of the same groups, which, it will be found, show a high mortality from consumption.

Overcrowding and low wages go hand-in-hand with casual labour. Both these conditions have frequently been shown to have a close relation with high phthisis mortality. They have come to be accepted as inevitable and normal in many grades of workers in our civilised communities. The political economy of this part of the question is a matter for the statesman rather than the physician, and I do not intend to touch upon it further here, beyond saying that it is not for medical men to look upon it as a satisfactory state of things or one which should be regarded with complacency.

Phthisis as a disease of occupation can be considered firstly as to its comparative mortality in different occupations, and secondly as to the comparative percentage of deaths it causes in different occupations.

Firstly, and this is the only accurate way, we can compare the actual mortality from phthisis in different occupations by figures calculated for the purpose of comparison from the actual death-rates per 1000 living.

Secondly, we can take the point of view which compares the percentage of the total deaths which occurs from phthisis in one occupation with the percentage which occurs in others. This comparison, of which medical authors have always been particularly fond, must be used with discretion, and is liable

[1] This paper is based on part of a report on "Phthisis as a Disease of Occupation," presented to the Second International Congress on Industrial Diseases, Brussels, September, 1910.

to lead to wrong conclusions. For instance, if an occupation be healthy as regards phthisis, but unhealthy in regard to other respiratory diseases, and perhaps to many other causes of death, phthisis would form a small proportion of the total causes of death, and yet the number per 1000 living in that occupation who would be likely to die from phthisis might be greater than the average death-rate from phthisis of all classes per 1000 living. But it is an interesting figure when calculated as a percentage, in that it suggests for the particular occupation under consideration the proportion that will die of the disease, and in some groups affords a legitimate basis for comparison. On the other hand, if an occupation be particularly unhealthy as regards consumption and healthy as regards other causes of death, it is clear that phthisis will present a high proportion of the total causes of death, and yet the actual death-rates from phthisis in that occupation be no greater, or even less, than the average death-rate from phthisis per 1000 living, and the total death-rate of the occupation may be even less than the average total. In the following tables the occupations are classified in comparison with all males taken together. The figure used as a basis for comparison is, for all males from all causes taken together, 1000. This figure 1000, it must be clearly understood, is simply an expression as a basis of comparison; it can be divided into its component parts, the various causes of death, and in the statistics on which this paper is founded phthisis is represented for all males by the figure 186. In other words, of 1000 deaths of all males from all causes 186 are due to phthisis (18·6 per cent.).

Another useful comparative figure is that of the agriculturist, which is, for all causes, 602, and for phthisis 85 (14 per cent.). The agriculturist is, as a labourer, among the worst paid, worst fed, and worst housed of the working classes, yet his largely outdoor occupations and freedom from overcrowding, and hence lessened intensity of infection, render his figure of comparative mortality from consumption a standard for measurement of other occupations.

In the following tables each group of occupations is arranged in the order of the comparative mortality from phthisis. The percentage of deaths from phthisis have also been calculated and placed in a column by the side of the comparative mortality figures. The comparative mortality figures are those given in the official returns.[2]

GROUPS OF FIGURES SHOWING—

For Ages 25–65.

Comparative mortality, all causes.	Comparative mortality from phthisis.	Percentage of phthisis.	Occupation.	
1000	186	18·6	All males.	Standards.
925	175	18·6	Occupied males.	
602	85	14·0	Agriculturists.	
			Professional Classes.	
515	53	10·2	Clergymen.	
952	65	6·8	Physicians and surgeons.	
739	87	11·8	Barristers.	
599	99	14·9	Schoolmasters and teachers.	
760	138	18·0	Artists, engravers, sculptors, architects.	
907	161	17·7	Commercial travellers.	
1140	301	26·0	Musicians and music teachers.	

In the above group it is interesting to note that the last class has also double the average mortality from alcoholism.

		Clerks and Officials.	
586	73	13·0	Gamekeepers.
723	129	17·8	Civil Service clerks and officials.
707	153	22·0	Railway officials, clerks.
791	160	20·2	Civil Service messengers.
815	178	21·9	Domestic indoor servants.
837	181	22·0	Commercial clerks, insurance clerks, &c.
880	237	27·0	Law clerks.
1341	368	27·0	Messengers, porters (not railway or Government).

[2] Dr. Tatham's Supplement to the Sixty-fifth Annual Report of the Registrar-General.

In these classes the only out-door occupation, the gamekeeper, introduced for comparison, has a large pre-eminence in health. Of the rest, a post under Government carries great advantages, partly due to selection by medical examination. The last class (which has double the average alcoholism) includes many weaklings and failures in other callings, but the law clerk is nearly as bad and shows a high phthisis mortality with a low general mortality. His alcoholism is half the average.

Agricultural Classes.

Comparative mortality, all causes.	Comparative mortality from phthisis.	Percentage of phthisis.	Occupation.
562	71	12·6	Farmers, graziers.
572	82	14·3	Farm labourer, farm servant.
551	82	15·0	Labourer (agricultural districts).
527	83	15·7	Gardener, nurserymen, seedsmen.
602	85	14·0	Agriculturists.
			Transport Service.
582	63	10·8	Railway engine-driver, stoker.
892	96	10·7	Fisherman.
773	111	14·3	Railway guard, porter, pointsman.
1235	157	12·8	Bargemen.
1094	169	15·4	Carmen, carriers.
984	186	19·0	Tramway service.
1062	216	26·0	Coach, cab, omnibus service.
1547	249	16·0	Seamen, &c. (Merchant Service).

In the above two groups engaged in outdoor occupations (fishermen being introduced for comparison with the transport service), the two last also have excessive alcoholism. Both seamen and bargemen have 4–4½ times the average accident mortality. Nearly all classes in these two groups are below the average phthisis mortality, but the agricultural classes are pre-eminently healthy, only being equalled by the learned professions as regards phthisis, and having a lower general mortality than all except clergymen.

Shopkeepers.

Class I.—Such as are largely engaged in open shops or out of doors.

776	90	11·6	Milkmen, cheesemongers.
882	151	17·0	Fruiterers and greengrocers.
943	158	16·7	Fishmongers, poulterers.
1062	172	16·2	Butchers.
1778	516	29·0	Costermongers, hawkers.

The protective influence of fresh air is well shown here, all but the last class having phthisis mortality below the standard of all males. The percentage of phthisis deaths is also low in all but the last class. This class includes many of the very poor, and many weaklings and failures in other occupations. In this class alcoholism is also high, being twice the average. Fishmongers and fruiterers have one and a half and butchers twice the average amount of alcoholism mortality. Milkmen are below the average in alcoholism.

Class II.—Such as are Largely Engaged in Closed Shops or Indoors.

734	100	13·6	Maltster.
67	115	17·0	Grocer.
852	156	17·8	*Baker and confectioner.
817	183	22·0	Watch, clock, scientific instrument maker, and jeweller.
755	188	24·9	*Draper, linen-draper, mercer.
872	200	23·0	Stationer, publisher, newsagent, stationery manufacturer.
889	213	23·9	*Saddler and harness-maker.
953	236	24·7	*Tailor.
898	237	26·0	*Tobacconist.
1070	253	23·6	*Hairdresser.
901	256	26·0	Shoemaker
1046	272	26·0	*Hatter.
1274	314	23·7	*Furrier and skinner.

These indoor shopkeepers, some of whose trades may be called (*) "dusty occupations," show a general high phthisis mortality, both actual and expressed as percentages. All have a low alcohol mortality, except the hairdresser and furrier, where it is a little above the average. Confinement (and in some classes foul air and dust) and the physique of those engaged in these trades are the causes of the phthisis excess.

The Liquor Trade.

Comparative mortality, all causes.	Comparative mortality from phthisis.	Percentage of phthisis.	Occupation.
1324	246	19·0	Brewers.
1562	247	15·6	Innkeepers, &c. (London).
1945	249	12·8	Innkeepers, &c. (industrial districts).
1669	252	15·0	Innkeepers, publicans, wine, spirit, and beer dealers (all districts).
1901	275	14·4	Innkeepers, servants, &c. (masters and servants together; industrial districts).
1415	278	19·0	Innkeepers (agricultural districts).
1410	288	20·0	Innkeepers, servants, &c. (masters and servants together; agricultural districts).
1697	306	17·0	Innkeepers, servants, &c. (masters and servants together; all districts).
1083	410	38·0	Inn and hotel servants only (agricultural districts).
1691	426	25·0	Inn and hotel servants only (industrial districts).
1814	443	24·0	Innkeepers, servants, &c. (masters and servants together; London district).
1767	533	30·0	Inn and hotel servants only (all districts).
2121	680	32·0	Inn and hotel servants only (London district).

Those engaged in the selling of alcohol have an excessive general *and* phthisis mortality in every case. In all, alcoholism is greatly in excess, being seven times the average in the dealers (masters) and nine times the average in the servants (all districts). The latter have twice the phthisis mortality of the former, perhaps on account of worse food and housing. Confinement, foul air, and alcoholic excess are the causes of high phthisis mortality in the liquor trade. "La phthisie se prend sur le zinc."

Textile Industries, &c.

684	139	20·3	Paper manufacture.
927	157	16·0	*Wool, worsted manufacture.
942	167	17·0	*Carpet, rug, felt manufacture.
826	172	22·7	*Rope, cord, twine manufacture.
831	183	22·0	Lace manufacture.
1066	184	17·2	*Dyer, printer, bleacher, and finisher.
1037	192	17·2	*Cotton manufacture.
892	199	22·0	Silk, satin, crape manufacture.
853	211	24·7	Hosiery manufacture.
1216	325	26·7	*Brush, broom makers, hair and bristle workers.

Several of these occupations are carried on (*) in foul and dusty air. The phthisis mortality is not largely different from the standard of all males, but the last class shows a heavy figure. This class includes a number of poor workers who are not addicted to alcoholism in excess, and there is less than the average alcohol mortality in all the classes of this group, except the lace-workers, in whom, including liver affections, there is a slight excess. In papermakers the alcoholism is very low.

The tables which follow are arranged in nine classes: (I.) Wood-workers; (II.) printers and allied trades; (III.) steel- and iron-workers; (IV.) metal-workers; (V.) coal-workers; (VI.) building trades, &c.; (VII.) miners and quarrymen; (VIII.) glass-, tile-, and earthenware-makers; and (IX.) other mechanics.

Mechanics and Artisans.

Comparative mortality, all causes.	Comparative mortality from phthisis.	Percentage of phthisis.	Occupation.
		Class I.—Wood-workers	
717	114	15 8	Sawyer.
774	124	16·0	Coach, carriage, railway-coach builder.
757	138	18·0	Wheelwright.
769	144	18·0	*Carpenter and joiner.
888	217	24·0	*Cabinet-maker.
1104	263	22·9	*Wood-turner, cooper.

The last two classes only show an excess of phthisis mortality. Some of these occupations (*) are classed as "dusty." All are below the average in alcoholism.

		Class II.—Printers and Allied Trades.	
910	240	26·0	Lithographer, copper, and steel-plate printer.
889	273	30·0	Bookbinder.
935	290	31·0	Printer.

All these industries involve foul air. They do not present excessive alcoholism. All have a low general mortality with a high phthisis mortality.

		Class III.—Steel- and Iron-workers.	
723	85	11·7	Engine-driver, stoker, fireman (not railway, marine, nor agriculture).
765	121	15·8	Shipbuilding.
971	142	14·6	Boiler-maker.
884	152	16·8	*Blacksmith, striker.
866	157	18·1	Engine, machine, boiler-maker, fitter, millwright.
848	160	18·8	Engine, machine-maker, fitter, millwright.
1137	182	15·7	*Nail, anchor, chain, and other iron and steel manufacture.
762	206	27·0	*Cycle and motor manufacture.
890	214	24·0	*Lock, key, gas-fitting maker, gas-fitter.
1087	223	20·5	*Gunsmith.
1231	353	28·6	*Tool-, scissors-, file-, saw-, needle-makers.
1602	375	22·8	*File-maker.
1460	516	34·0	*Cutler, scissors-maker.

Some of the above occupations (*) are classed as "dusty." All except the gunsmith have less than the average alcoholism. On the whole the steel- and iron-workers show less than the average phthisis mortality.

		Class IV.—Metal workers.	
1041	160	14·8	Copper manufacture, worker, coppersmith.
1385	166	11·7	Lead manufacture, leaden goods worker.
977	206	21·0	Copper, tin, zinc, lead, brass manufacture and worker.
974	209	21·0	Tin-plate manufacture, tin-plate goods worker.
889	230	23·0	Zinc manufacture and worker.
1074	262	23·4	Brass, bronze manufacture, founder, finisher, worker.

All of these occupations involve foul and dusty air. The lead industry has more than double the average alcoholism. All the other classes have less than the average alcoholism. The general excessive phthisis mortality is due to the foul and dusty air.

		Class V.—Coal-workers.	
846	85	10·0	Coal-miner.
695	88	12·6	Coal merchant, coal burner.
838	135	16·0	Gasworker service.
1144	206	17·4	Coalheaver.
1240	263	21·0	Chimney sweep.

Of these, all are "dusty" occupations. The general and phthisis mortality are both low except in the last two cases. In both of these alcoholism is high, being twice and three times the average respectively. Coal dust seems to be less obnoxious to the lungs than metallic dust or stone dust.

Comparative mortality, all causes.	Comparative mortality from phthisis.	Percentage of phthisis.	Occupation.
			Class VI.—Building trades, &c. (other than Class I.).
1036	187	18·0	Slater, tiler.
862	188	21·4	*Bricklayer, mason, builder.
1041	203	19·0	Plumber, painter, glazier.
937	205	21·8	Paperhanger, plasterer, whitewasher.

Only one class is marked as "dusty."* The only class showing alcoholic excess is the last.

			Class VII.—Miners, quarrymen.
723	126	16·9	Ironstone miner.
905	186	20·2	Stone, slate quarrier.
1199	317	26·8	Lead miner.
1609	501	34·4	Copper miner.
2169	838	38·0	Tin miner.

All of these are dusty trades, involving sharp metallic particles. All have less than the average alcoholism, except the copper miner, whose alcohol mortality is three times the average.

			Class VIII.—Glass, tile, earthenware-makers.
622	72	11·5	Brick, plain tile, terra-cotta worker.
1202	269	22·6	Glass manufacture.
1420	277	19·0	Potter, earthenware, &c., manufacture.

All of these are more or less dusty trades. All have less than the average alcohol. The first is largely an outdoor occupation.

			Class IX.
1031	96	9·2	Chemical manufacture.
689	108	15·6	Tallow, soap, glue, manure manufacture.
737	132	17·9	Tanner.
944	199	21·0	Currier.

All of these have less than the average alcoholism and phthisis. Other respiratory diseases are very high in the case of the chemical manufacture.

			Labourers.
707	91	12·8	Platelayer, railway labourer, navvy, &c., road labourer.
1374	291	21·0	Dock labourer, wharf labourer.
1987	450	22·6	General labourer.
1808	531	29·0	General labourer, London.
2471	567	22·9	General labourer (industrial districts).

With the exception of the railway workers all these classes show a very great excess of phthisis. In the railway workers and road labourers alcoholism is less than half the average. In all the other groups it is about three times the average. All these groups include some of the poorest workers, badly housed and fed, and many who have been failures in other occupations, or who have drifted on account of alcoholism, or by reason of lack of qualities making for stability. The general labourer class forms about $\frac{3}{5}$th of the adult male population, and incurs about $\frac{1}{5}$th of the total phthisis mortality.

From the accompanying general review and re-arrangement of the Registrar-General's figures for male adults regarding the occupational mortality from phthisis (see Table), we can gather that there is a distinct relationship between certain kinds of employment and phthisis mortality. The one great preventive is fresh air. Apart from certain highly special conditions involving the respiration of sharp, metallic particles (e.g., the tin-miners), the highest mortality from phthisis is associated either with the trade in alcohol, or with the occupations which are the refuge or the penalty in the struggle for existence of the least competent. The unskilled workers and labourers, the street sellers, and similar classes on the one hand, and systematic poisoning with alcohol on the other, cause a phthisis mortality of three to four times that of All Males, and six to eight times that of the agriculturist. In these classes phthisis is part of a high general mortality.

SOME COMPARATIVE EXAMPLES OF LIFE WASTAGE BY PHTHISIS.

Occupation.	Average age at death from all causes.	Average age at death from all causes (excluding phthisis).
Clergymen.	63·0	64·0
Musicians and music masters.	48·0	50·0
Schoolmaster and teacher.	46·7	50·0
Railway official, clerk.	45·0	48·7
Law clerk.	44·4	48·3
Commercial clerk.	42·4	46·2
Messenger and porter (not railway or Government).	47·0	50·0
Innkeeper (London).	45·0	49·0
Inn, hotel, servants (London).	39·0	42·0
Costermongers, hawkers.	50·0	52·3
Printers.	44·0	48·4
Cycle and motor manufacture.	35·0	38·0
File maker.	52·0	53·0
Hatter.	48·0	52·0
Hairdresser.	42·6	44·2
Shoemaker.	54·5	58·0
Tin miners.	51·0	54·0
Engine-machine fitters.	48·0	51·0

But we also find that there are many industries whose mortality as a whole is low and yet their phthisis mortality is about or above the average. Phthisis in these classes, therefore, forms a high percentage of total causes of death. Typical instances of these occupations are clerks, indoor shopkeepers, many of the textile industries, the printing trades, and those working in metals other than iron and steel. Confinement, foul air, metallic dust, bad housing, and other conditions inherent to the occupations are the causes of the phthisis excess.

In writing on the eventual conquest of consumption medical writers and laymen interested are prone to deal with it too exclusively from the point of view of infection. This involves the idea that by treating the early cases and segregating the advanced cases this great scourge of all civilised communities can be eradicated. To me, though I believe that much could be done along such lines, it seems that the greater part of the question would remain untouched. To secure a regular and systematic examination of every employee, as is now attempted in the case of school children, is at present a counsel of perfection, even if sufficient skilled observers were available to make the necessary early diagnosis. To attempt to segregate all the comparatively advanced cases would involve a great deal of concealment in the present state of popular ignorance. Compulsory notification is an essential first step in the discovery of the real number of the phthisical population.

The widest possible health teaching among the poorest and most ignorant classes of the people, and the most careful regulation of all the conditions under which the more or less skilled but yet unhealthy industries are carried on, are also essential preliminaries to the real stamping out of consumption. As the sanatorium is the basis of all successful curative treatment of tuberculosis, so a knowledge of sanatorium methods must be universally disseminated and acted upon as the basis of its prevention. The people must learn for themselves, and it is the duty of all interested in this subject to help them. Consumption is not to be regarded as on the same plane of infectivity as those diseases from which knowledge, good food, leisure, and healthy surroundings do not protect. Such diseases are much more easily controlled by segregation methods. The mass of conditions comprehended in the term "environment" is at least as important

as (and perhaps the figures I bring before you may suggest, even more important than) infection in the case of tuberculosis of the lungs. The revealed case of phthisis, if it be of the curable class, should be taken from the workshop and home to the sanatorium. But to prevent its occurrence much more is necessary; the lessons of the sanatorium must be enforced in the workshop and the home.

The sanatorium is an object-lesson for those who are not consumptive and a school of healthy living for those already affected; it cannot remedy the existing conditions of those most susceptible to the disease. It is these conditions which form the real problem for the statesmen whose care is that of the public health. Where the occupational surroundings are known to be conducive to the development of phthisis the workshop, office, and home must be regulated into at least as wholesome a condition as the coal mine or inspected factory. As a disease of society tuberculosis lies latent in the infected house and the insanitary workshop, ready to attack the weaklings, just as it lies latent in the human body seeking a favourable moment to invade the tissues. The citadels of this ubiquitous enemy must be defined and destroyed, and the humble privates in our ranks must not be exposed to its ravages undefended by the entrenchments of hygiene. One cannot win such a campaign by caring for the wounded only. We must not regard the casualties as inevitable. The disease is dying a natural death with improved conditions of the working classes, and it is by further development on such lines, and not otherwise, that its extermination will be attained.

Brook-street, W

MINERAL WATERS AS ARTIFICIAL SERA:

A SHORT ACCOUNT OF INVESTIGATIONS ON THE QUESTION OF MINERAL WATERS AS ARTIFICIAL SERA AND OF INJECTIONS OF MINERAL WATERS INTO THE TISSUES BOTH FROM A PHYSIOLOGICAL AND A THERAPEUTICAL POINT OF VIEW.

BY DR. C. FLEIG,

CHEF DE LABORATOIRE À LA FACULTÉ DE MÉDECINE DE MONTPELLIER.

(*Translated by* H. DE MÉRIC, M.R.C.S. Eng., *Surgeon to the French Hospital, London.*)

I HAVE the honour of bringing forward a short account of the investigations, both experimental and clinical, that I have undertaken during several years on the question of utilising mineral waters as artificial sera, and I have grouped together in the present paper the various series of facts which have led me, as a practical conclusion, to extol the employment of mineral waters as injections into the tissues. This, I may add, is from a double point of view: (1) their application as artificial sera, and (2) as a new method of carrying out hydro-mineral treatment.

These investigations are of interest with regard not only to so-called hydrology but also to therapeutics and physiology. Space will not allow me at present to dwell on the question of the birth of the idea which led to the utilisation of mineral waters as injections into the tissues, or to enter into details concerning the researches of various authors who have taken up the question of mineral-water injections, such as Glénard, Billard and Ferrey-Rolles, R. Trémolières, and others. I must content myself therefore in the present paper with indicating the most important points of my experiments. I will only say that it was through my investigations on artificial sera with complicated mineralisation and the results in general obtained by injections of sea water that I was led to the idea of the mineral waters themselves being utilised as artificial sera.

Mineral Waters in Reference to their Employment as Artificial Sera or as Vital Plasma.

The mineral waters which I have used up to the present for the study of this question are hypotonic, isotonic, and hypertonic, and correspond to many different chemical compositions, most of them, however, from a qualitative point of view approaching to a certain extent the composition of the blood plasma. As these waters, by reason of certain of their properties (electrical, colloidal, radio-active, or others little known or absolutely unknown), can be looked upon as "living" at their exit from the springs from which they rise, they can be used as injections at their issue in an aseptic condition without preliminary sterilisation, thus avoiding the slightest change in their natural condition and any possible modification of their "living state." In the event of sterilisation being necessary, it should be done at a low temperature by filtration through candles (filtration by compression by means of Chamberland's apparatus; filtration under pressure more or less strong of CO_2, of hydrogen, or of air with an intermediary isolating stratum of oil, this being excellent for bicarbonated, ferruginous, or sulphurous waters; filtration under pressure of oxygen or of other gases for special cases). Undoubtedly the best plan for keeping the water is in sealed flasks made of yellow or red glass.

The waters which hold insoluble mineral elements in suspension should be reserved for subcutaneous or intramuscular injections. In these different ways either hypotonic, isotonic, or hypertonic waters can be employed according to the effect to be brought about. In order to render hypotonic waters isotonic either chloride of sodium, sea water, very salt mineral water, or sugar can be employed. The waters to be injected can be utilised with their gases in solution; this has a certain amount of interest in the case of waters containing rare gases.

Theory and Experimental Demonstration of Mineral Waters as Vital Plasma or Artificial Sera.

The conception of mineral waters as vital plasma and as artificial sera rests on a triple series of facts: (1) the facility of their injection in enormous quantities and by every possible channel, both in animals and in man; (2) the effects of their transfusion after copious blood-letting in animals and in man; and (3) the examples of the survival and reviving of organs or of cellular elements isolated from the body and placed in mineral waters.

1. Any mineral water can be injected, even in large quantities, into the tissues or into the blood. This conclusion is based on the results of copious and repeated intravenous injections given to animals, especially of prolonged and moderately rapid injections. The phenomena of diuresis, particularly observed under the influence of the latter, show that most mineral waters whose action has been studied are media even less toxic than ordinary normal salt solution, and that the changes they effect in the natural intracellular vital plasma are even less than those brought about by simple salt solution. Comparative experiments have shown that these diuretic phenomena are analogous to those which follow isotonic injections of sugar. On the other hand, mineral waters, the composition of which is to a certain extent different both quantitatively and qualitatively from the mineral composition of the blood plasma, can, notwithstanding, be injected in large quantities into the blood, and this allows of their employment as artificial sera which satisfy certain special indications. The fact of the feasibility of injecting mineral waters in large quantities without any toxic effect seems to be generally acknowledged, and this gives to the proceeding itself a value of great interest. It must be specified, however, that all these results are supported solely by experiments carried out with water sent some distance from its source and not with waters injected directly at the locality where they issue from the spring.

2. With human beings in those cases where after hæmorrhage injections of normal saline solution are indicated, injection into the veins of pretty large quantities of various suitable mineral waters is accompanied by no injurious action on the corpuscles, but, on the contrary, by very beneficial effects both on the blood and on the circulation.

3. Many mineral waters, at a suitable state of molecular concentration, are capable of preserving the excitability and of maintaining the spontaneous movements of organs having unstriped muscular fibres and furnished with glands (such as the intestines, the uterus, the bladder), when these parts are completely separated from the body and simply immersed in these waters. The intensity of the contractions is often stronger with mineral waters than with salt solution. These mineral waters play the part of specially exciting media, for, at the beginning of the immersion, the intestine contracts better in mineral water than in saline solution; and, still more, after it has remained for a long time in saline solution and so has become motionless, it will even then contract much more forcibly if plunged into mineral water.

Some waters, however, can exercise an inhibitory action owing to the preponderance of some of their elements (Mg), but even in such cases there is no question of any toxic action; intestine contracts again excellently when moved into suitable media.

The action of temperature on the contractions, in mineral waters, of organs having unstriped muscular tissue is the same as that noticed under identical conditions on the contractions of these organs in various artificial sera of complex mineralisation (highest temperature 38° to 39° C., the contractions begin at 25° to 26° C., and continue even down to 15° C., if after the organ has begun to contract it is slowly cooled). If the organs are kept at a low temperature in an ice-house, contractions by immersion in mineral waters can still be obtained by progressive heating, even after eight or nine days. The same phenomena as those manifested in the revival of contractions in the intestine when placed in complex artificial sera are also observed in the revival of contractions in mineral waters (a sudden revival at about 20° to 23° C., the second maximum temperature being about 35° C.). The same waters show a great superiority to salt solution with regard to spontaneous contractions of the ureter in guinea-pigs.

Organs with striated muscular fibres also retain their excitability for a longer period in mineral waters than in ordinary salt solution, and exhibit under the influence of the former stimulus much stronger contractions than when submitted to the action of the latter; this is the case, for example, in muscles of the bony skeleton when stimulated by artificial circulation, and also in a rabbit's œsophagus when simply immersed in these media. After being treated with mineral waters and kept in an ice-house the œsophagus can still be made to contract by electrical stimulus, even after it has been detached from the body of the animal for eight days. Finally, the contractions of the excised heart of a frog are much stronger under the influence of various mineral waters than under that of simple saline solution.

Investigations into the action of isotonic mineral waters, deprived of any possible excess of CO_2, on isolated cellular elements, such as red blood corpuscles or spermatozoa, prove that these waters do not exercise a toxic action on the living cell. Red blood corpuscles submitted to centrifugal action and to successive decantation, in which various mineral waters are the liquids employed, remain in a vital condition in these media. When reinjected, whilst in suspension in these same waters, into the animal from which they have been taken ("auto-transfusion") or into another animal of the same species ("iso-transfusion"), they revive it admirably, even after a blood-letting, which, if treated simply with transfusion of normal saline solution, would inevitably have proved fatal. Similar transfusions can be repeated several times on the same animal without the slightest manifestation of any bad effect or of any deleterious action of the mineral water on the red corpuscles. (Corpuscles, bathed in this way by mineral water and then transfused, are undoubtedly in a vital condition, preliminary investigation having proved to me that transfusion of corpuscles which preserve their physical characteristics but which have previously been submitted to some deleterious action does not bring about the survival of the animal.) Corpuscles that have remained in contact in a refrigerator for several weeks, but which all the time have been immersed in mineral waters, are still capable of producing the same reviving effects as fresh corpuscles.

In man auto-transfusion of corpuscles that have been immersed in mineral waters, practised after abundant and repeated blood-lettings, permits the withdrawal from the diseased organism of large quantities of serum (the toxic part of the blood), and thus the carrying out of a true lavage of the blood by means of merely a loss of serum, this, too, without bringing about the slightest anæmic condition of the individual; this happened in a case of grave uræmia. These repeated auto-transfusions are not accompanied by any deleterious action on the corpuscles. (Results of a similar nature are obtained with auto-transfusion of corpuscles kept in suspension in various complex artificial sera or in normal salt solution.) We have here to deal with a general method which, to my mind, can be of great service in all cases of disease where the serum has a high toxic power (endo- or exo-genetic intoxications, infections, &c.).

Human spermatozoa that already show at an ordinary temperature very intense movements retain their vitality much better in mineral waters than in pure salt solution. This conclusion is based: (1) on a study of the movements of spermatozoa immersed (like red corpuscles) in mineral water and in pure salt solution; (2) on the study of their movements in a mixture of spermatic fluid and of more or less large quantities of mineral water; and (3) on the study of their revival in these last media after having been kept several days at a low temperature (movements still seen eight days after emission of the spermatic fluid). The superiority of mineral waters over simple normal salt solution is due to their complex mineralisation and to the specially important action of some of their elements, such as calcium; this last is necessary not only for the production of contractions in organs having unstriped muscular fibres (to a less degree in those having striped muscular fibres), but also for the movements of the spermatozoa, as I have demonstrated in several experiments.

These successive series of investigations appear to me to establish on a sufficiently solid basis the conception of mineral waters as artificial sera and vital media. Moreover, this conception coincides very well with the theory of sea-water acting as a vital medium, for many mineral waters clearly have a pelagic origin.

Some Physiological Effects of Mineral Waters as Artificial Sera.

Other physiological effects, differing from those just referred to with reference to the utility of mineral waters as artificial sera, allow us to show that the action of mineral waters from this point of view is often more powerful than that of normal salt solution. The phenomena of reaction produced in man after injections of considerable quantities of mineral waters are undoubtedly more marked than those following injections of the same quantities of simple saline solution. Their intensity, too, is greater in proportion to the greater hypertonicity of the waters injected.

On the blood and on the circulation injections of mineral waters exercise an action recalling mostly that of those artificial sera which have a complex mineralisation, notably with regard to coagulation and to the renovation of the blood corpuscles, also with regard to blood pressure and to cardiac contraction.

The increase in the coagulability of the blood both *in vivo* and *in vitro* under the influence of various mineral waters is much more evident than that produced by simple salt solution. A difference of the same kind shows itself in the hæmostatic action brought about by these same waters and that by salt solution when either is injected in cases of profuse hæmorrhage produced, for example, by transverse sections of muscles. These facts are in a great measure explained by the richness of these waters in lime salts. The mechanism of the hæmostatic action set up *in vivo* is double, being due, on the one hand, to the increase in the coagulability of the blood, and, on the other, to the agency of a vaso-constrictor mechanism.

The comparative effects of injections of ordinary saline solution and of injections of mineral waters on the renovation of the corpuscles, studied by means of two series of experiments, tend to the conclusion that the renovation of the corpuscles is more rapid under the influence of injections of mineral waters, and that the renovating effects are also in the latter case superior to those of salt solution, producing a lasting revival of animals which, had only transfusion of ordinary salt solution been practised, would inevitably have succumbed.

On the blood pressure there is also a difference of action. Certain mineral waters when injected produce a persistent rise of pressure at doses which with salt solution have far from the same effect. This action must again be attributed partly to the calcium; the same may be said of their action on cardiac contraction, which is much more marked with intravenous injections of mineral waters than with similar injections of normal salt solution.

With reference to the modifications produced on the phenomena of excretion and of nutrition under the influence of mineral water injections, the general differences between them and the ones brought about by salt solution can be compared to those produced by those artificial sera which have a complete mineralisation and those brought about by simple salt solution. That is to say, as a general conclusion, many mineral waters show organic media which are preferable in all points to those of normal saline solution.

Radio-activity of certain waters, or their artificial radio-activation brought about by the addition of bromide of radium or by induction, does not modify this conclusion and does not represent in any way a factor of toxic or hurtful qualities, this being proved by the action of these waters on isolated contractile organs of the body, on the red corpuscles, or on the spermatozoa.

Deductions. Clinical Application of Mineral Water Injections into the Tissues.

The therapeutical employment of mineral water injections becomes then perfectly logical. In a general way they can be used both in cases where injections of normal saline solution or of isotonic sea-water are indicated, as well as in those in which we consider it of importance to apply a hydro-mineral cure, the maximum conditions of activity of which we wish to realise. Here I may recall the net results obtained in cases that I have already published of adenitis, tuberculosis, osteitis, pulmonary tuberculosis (certain forms), lymphatism, asthenia and anæmia, malaria, diabetes, chronic rheumatism, ulceration, eczema, psoriasis, severe syphilis with intolerance for mercury, glycosuria, and experimental tuberculosis.

In order to render a precise statement of the indications necessary for injections of mineral waters of different groups many clinical observations are requisite, but from the present time, by taking as a basis for our researches the investigations already carried out on injections of normal saline solution and on hydromineral treatment administered by the classical methods, we can foresee the series of cases in which the mineral waters would be indicated. Naturally it would be most interesting if we could choose the water which, from its chemical composition and from its various known properties, would seem best suited to the case under treatment; thus a kind of differentiation, becoming more and more distinct, would take place between the different groups of mineral waters (bicarbonated, sulphurous, &c.) to be employed as injections.

A most important study is grafted on to the last dicta: it is the comparison on the one hand between the effects produced by injections of mineral waters taken on the spot from the spring itself (in most cases without any modification), and on the other hand, the effects produced by injection of the same waters after a more or less prolonged interval since their exit from the spring. It would be of very great interest to be able to give precise data concerning in what proportion the results obtained with the "living" waters can be assimilated with those of the "old" or "dead" waters. In any case injection of mineral water into the tissues at the spring itself should be investigated on analogous lines to those employed in the experimental researches mentioned in this paper.

These advantages of injections of mineral waters into the tissues as a method of so-called cellular balneotherapy and of the application of the hydromineral cure in general are very numerous, as I have shown in detail, but the greatest discrimination is imperative in utilising these injections in certain cases, *as they cannot in any way be looked upon as substitutes for the methods of administration habitually employed*, although they are calculated to augment the activity of these last and to notably enlarge the field of application, already so extended, of hydromineral medication.

Finally, we must realise the first-rate benefits that hydrologic therapy will receive from physiological data, these last pointing to a line of investigations which at the present time are only at their dawn, the grand total of which, however, will probably form the basis of experimental hydrology.

LEWES VICTORIA HOSPITAL.—By the generosity of Mr. Augustus L. Christie a complete plant of the Roentgen rays has been installed at the Victoria Hospital on the Downs at Lewes. The new institution was opened on Feb. 2nd last by Princess Henry of Battenberg, and since that time the demands upon it have been exceedingly heavy, a fact accounted for by the up-to-date appliances. There has not, however, been a corresponding increase in the subscriptions, and at the annual meeting on Oct. 4th a strong appeal was made on behalf of the institution. It is to be hoped, too, that a little plain speaking by the mayor of the county town, in calling attention to a number of people who take no interest whatever in the hospital but are the first to appeal for letters for their domestics in times of need, will have the desired effect.

ULCERATING GRANULOMA OF THE PUDENDA A PROTOZOAL DISEASE.

BY R. MARKHAM CARTER, M.B., M.R.C.S. ENG., L.R.C.P. LOND., D.T.M. LIVERP.,
CAPTAIN, INDIAN MEDICAL SERVICE; OFFICIATING DIRECTOR, PASTEUR INSTITUTE OF INDIA.

Preliminary Communication.

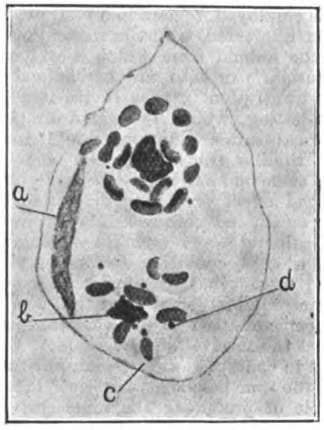
THIS interesting disease is one that is but rarely met with. It has taken some years to collect the material upon which the following observations have been made. Though the series of six cases is but a small one, it would seem sufficient to show that many of the views held by most observers regarding the etiology of the disease are entirely wrong.

Ulcerating granuloma of the pudenda is not a venereal disease, though, as a rule, the genitals and contiguous parts are the seat of infection. It is contagious and is auto-inoculated by the host on other parts of the body. The disease has been seen on the surface of the cheek, the buttock, &c. Maitland has described the disease as occurring within the buccal cavity, on the inner surface of the lips, gums, and inside of the cheek, but further confirmation of this distribution is necessary. The disease is usually seen in adults, and race plays no essential part in its etiology.

The distribution of the disease is extensive. It was first described by Conyers in 1896 in British Guiana, and later by Daniels in the South Pacific Islands. Northern Australia and New Guinea have given typical examples of the disease. It occurs in India perhaps more frequently than in other countries, and Maitland, Macleod, Powell Williams, and others have given us much literature on the subject.

According to former histological researches this disease has up to date always been classified amongst the infectious granulomatous tumours. However, if sections are stained as described below it will be found that the disease is due

FIG. 1.



An infected cell. *a*, Laterally placed nucleus of infected cell *b*, Deep-staining irregular central mass. *c*, Limit of clear area. *d*, Deep-staining dot. Drawn with 1/12 apochromatic and 8 compensating ocular Zeiss.

to a protozoal infection. Thin sections fixed to a slide are stained in a solution of Giemsa diluted 12 drops to 10 c.c. of distilled water. After this stain has acted for 20 minutes each section is washed in tap water for about 30 seconds, then dipped in eosin solution, 1 in 50,000, for 45 seconds, dehydrated, and brought up through xylol into Canada balsam. The second method is to stain a fixed section with a saturated solution of eosin in alcohol (95 per cent.) for five minutes; the solution must be three months old. The stained section is then washed in distilled water, and counter-stained with watery methylene blue, 1 in 1000, until the nuclei are stained deep blue. The slide is then washed in absolute alcohol for a few seconds and taken up through xylol into Canada balsam.

The first thing that strikes the eye will be that in certain areas lie masses of very large mononuclear cells, their cytoplasm distended with from 15 to 50 bean-shaped bodies resembling the gregariniform stage of a herpetomonas or crithidium. On using the higher powers of the microscope these bean-shaped parasites are seen to contain the usual cytological elements. The parasite, though slightly smaller than that seen in sections of Oriental sore, is very similar; and in the light of the recent work on Oriental sore, showing

FIG. 2.

Bean-shaped parasites on large scale. Drawn with 1/12 apochromatic and 12 compensating ocular Zeiss.

the crithidial monadine forms, &c., assumed by this protozoon, I consider that the parasite of ulcerating granuloma is of the same class, and will be found similarly to develop monadine and gregariniform phases in suitable culture media. For the present I propose, therefore, to consider ulcerating granuloma of the pudenda as due to a localised protozoal infection of man with either a herpetomonas or crithidium.

The parasites are found in large swollen cells, in which the nucleus is pushed to one side of the cell. The cytoplasm of the infected cells contains from 15 to 50 protozoal parasites arranged roughly in groups of 15 to 20, round a central homogeneous mass simulating the zooglia mass of Leishmania in cultivation. No flagella have been noted, but the fact that a deep staining dot lies external to and in close relationship with what seems to be the more mature form of the parasite is highly suggestive. The nuclei of the parasites stain a deep reddish violet, the dot almost black violet, and the cytoplasm of the parasite pale blue. The rest of the tissues in the neighbourhood of the infected area stain light blue. Lastly, it is interesting to note that each parasite seems surrounded by a faint unstained area suggestive of the similar appearance seen in staining for Negri bodies.

A CASE OF TUMOUR OF THE PITUITARY BODY.

BY WILLIAM BOYD, M.B., CH.B. EDIN.,
ASSISTANT MEDICAL OFFICER, DERBY BOROUGH ASYLUM.

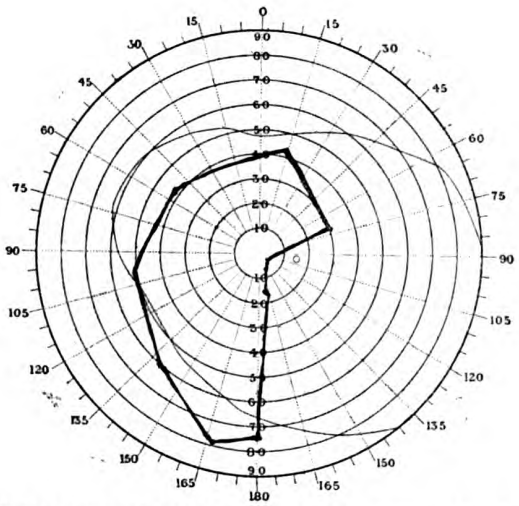
THE subject of tumours of the pituitary body has attracted a good deal of attention of late, and as the etiology and morbid anatomy of such tumours are still a matter of some obscurity, any case which serves to throw further light on the subject is deserving of attention. The condition of the cerebro-spinal fluid in such cases does not so far appear to have been noted, and this is one of several points of interest in the following case, for permission to publish the notes of which I am indebted to Dr. S. R. Macphail.

The patient, a man aged 36 years, married, was admitted to the Derby Borough Asylum on Dec. 22nd, 1909.

History.—Eight years ago the patient began to suffer from severe neuralgic pains, first in the left temple, and later in the right. Eighteen months later the sight in the left eye began to fail, and six months afterwards the right eye followed suit. The eye condition was treated in several hospitals, including St. Bartholomew's, at each of which large doses of iodide of potash were given, but both the sight and the headaches steadily became worse. In June, 1905, he began to have epileptic fits. There was no aura or local commencement; during the fit he bit his tongue and passed urine, and after the fit he fell into a deep sleep. Sometimes a succession of fits would occur, and he would pass into a condition of status epilepticus. In the course of the same year he had several mucous polypi removed from both nostrils. In 1906 he lost all sight in the left eye. In 1907 he became somewhat ataxic, and in the same year had an attack of acute mania, which has been followed by several attacks of excitement. During the last two years he has been gradually becoming more dull, stupid, and lethargic. In January, 1909, he lost all sight in the right eye. He has been getting very deaf, but for years has had a discharge from the right ear. In July, 1908, the middle ear was cleared out, but without benefit. He has always been a stout man, and has gained rather than lost weight during the present illness. His eyes are a good deal more prominent than they were a few years ago.

Condition on admission.—The patient was a strong, well-made man, with abundance of adipose tissue. The eyes were very prominent and staring. He was in a dazed and confused condition, unable to answer questions put to him, and requiring artificial feeding. He had no control of his vesical and rectal sphincters. Nothing abnormal was found in his circulatory, respiratory, and digestive systems. There was no polyuria, and his urine contained neither albumin nor sugar. From his left nostril there was a discharge of clear serous fluid, which appeared when he sat up in bed, and which fell drop by drop. It was highly albuminous, and on centrifuging was found to contain numerous leucocytes. As regards his nervous system, no paralysis of the arms or legs could be detected, nor any definite disturbance of sensation. He was very ataxic, even when sitting up in bed, but did not sway more to one side than to the other. The superficial reflexes were normal, but the deep reflexes were considerably exaggerated, those in the left leg being the most active. There was slight ankle clonus on the left side. The plantar reflex was flexion. Owing to his mental dulness it was not possible to test his cranial nerves with accuracy. There was weakness of all the extrinsic muscles of the left eye, the weakness being most marked in the superior rectus, internal rectus, and inferior oblique. The pupils were medium in size, equal, regular, and reacted well to accommodation; the reaction to light was very sluggish in the right eye and completely lost in the left. There was complete amblyopia, and double primary optic atrophy, this primary atrophy having been also observed in 1905 by Mr. Holmes Spicer at St. Bartholomew's Hospital. The blindness being complete, no observations could be made on his fields of vision, but fortunately some observations made in 1903 were available. These show that at that time the left eye was only capable of perceiving hand movements, while the right field of vision presented a beautiful example of hemianopia, the temporal half of the field being quite blind. (Fig. 1.) At that time he

FIG. 1.



Field of vision of the right eye, showing the temporal hemianopia.

is reported to have had choroiditis in both eyes. The earliest note of his ocular condition was in May, 1902, when his vision was normal and his fundi presented no unusual appearances. There was very marked deafness on both sides, but

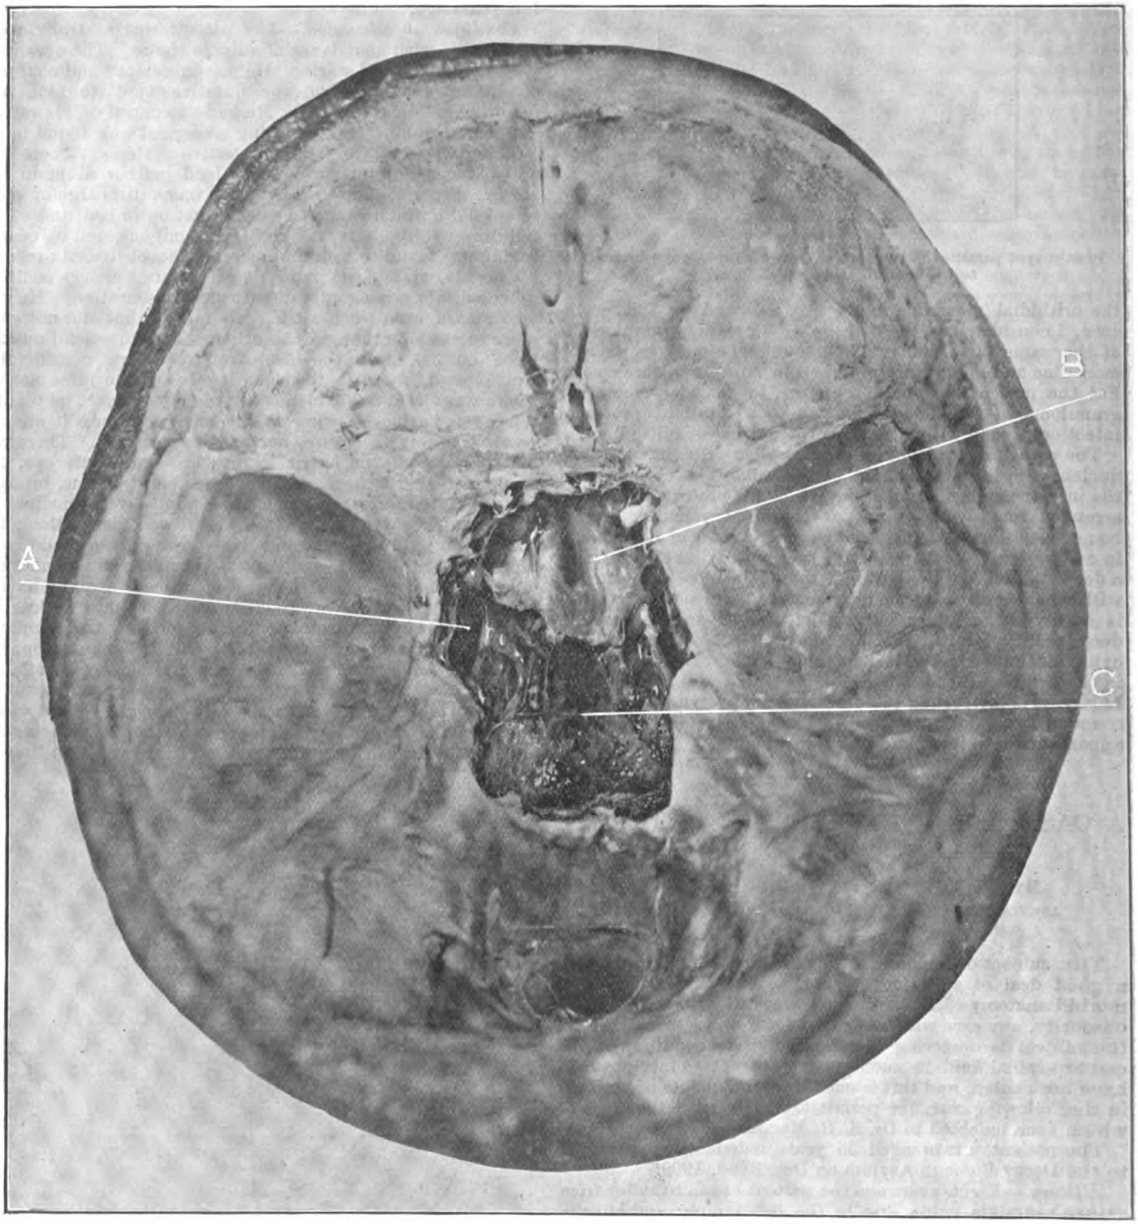
whether of middle-ear or nervous origin could not be determined.

The condition of the cerebro-spinal fluid was extremely interesting. It came out under markedly increased pressure, was quite clear, and contained an enormous quantity of albumin. The Noguchi test was positive, and with Jones's ammonium sulphate ring test a positive reaction was obtained with a dilution of 1 in 15, the amount of albumin thus greatly exceeding that usually found in general paralysis and tabes. Even more startling was the leucocyte count, which gave an average of 1630 per field under a magnification of 450 diameters, practically all the cells being lymphocytes.

Subsequent course.—After a few days the patient emerged somewhat from his condition of stupor and regained control of his bladder and rectum, but he was dull, stupid, and confused until his death. He continued to have typical epileptic fits at intervals of a week or so; no sign of localising value was observed in any of the fits. The pupils varied considerably in size from day to day, and at times were unequal and irregular. After remaining in very much the same condition for four months he died with startling suddenness, simply turning over on his side in bed and expiring without a struggle or groan, and with nothing to show that he was in other than his usual condition.

Post-mortem examination.—The body was well-nourished and covered with a liberal supply of fat. There were no signs of disease in the thoracic and abdominal organs. The skull-cap was uniformly thickened, and the dura mater was adherent to it in places. The pia-arachnoid stripped easily.

FIG. 2.



Floor of skull, showing enlargement of pituitary fossa caused by erosion of the tumour. A, Communication with the antrum of Highmore. B, Body of sphenoid. C, Cavity.

At the base of the brain there was a large, soft, friable vascular tumour of a fleshy colour, which was growing downwards into the sella turcica, from which cavity it had to be torn before the brain could be removed. A mass of pulpy vascular material, not unlike red currant jelly, was left in the pituitary fossa. The tumour was then seen to be growing from the infundibulum, this being the only point at which it could not be separated from the brain. It was invested by a thin delicate membrane, which, however, had been torn away in places, leaving a granular surface exposed. In consistency it was gelatinous, and was in places almost cystic. Its length was 7·2 cm., its width 3·3 cm., and it extended from the optic chiasma to the middle of the pons, occupying rather more of the left than of the right side. The optic chiasma had been crushed out of recognition, the crura widely separated, and the pons greatly distorted. The most striking changes, however, were those in the floor of the skull. (Fig. 2.) The sella turcica had developed into a huge cavern 6·5 cm. long and 4 cm. wide. Opening out of it on either side was an oval aperture, that on the left side proving on investigation to communicate with the antrum of Highmore of that side. Thus the discharge from the left nostril, observed during life, was in reality an escape of cerebro-spinal fluid from the cranial cavity. The fossa had no bony floor, but merely a membranous partition separating it from the cavity of the pharynx. Microscopic examination of the tumour showed it to consist chiefly of large round and oval cells containing a large and distinct nucleus; there were numerous large thin-walled blood spaces, and here and there fibrous trabeculæ running through the tissue; the whole bore a close resemblance to a mixed-celled sarcoma.

The chief points of interest in the case were: (1) the long duration; (2) the absence of wasting and of any symptoms of acromegaly; (3) the sudden termination; (4) the nasal discharge of cerebro-spinal fluid; (5) the enormous amount of albumin and extraordinary lymphocytosis in the fluid from a case of nonsyphilitic tumour (for the naked-eye and microscopic characters, together with the resistance to large doses of potassium iodide, clearly point to the non-specific nature of the growth); and (6) the remarkable destruction to the floor of the skull.

Rowditch, Derby.

A CASE OF

CARCINOMA OF THE CÆCUM REMOVED AFTER A PRELIMINARY EVACUATION OF A FÆCAL ABSCESS AND AN ILEO-SIGMOIDOSTOMY; PATIENT WELL A YEAR LATER.

BY JOHN D. MALCOLM, M.B., C.M. EDIN., F.R.C.S. EDIN.,

SENIOR SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE patient, a short stout man, 64 years of age, was sent to me on March 24th, 1909, by Dr. R. D. Mackintosh of Mortlake. He had for eight years been subject to attacks of pain in the right side of the abdomen which began suddenly and were accompanied by vomiting, retching, and constipation. The abdomen distended and weight was lost rapidly, but the temperature was never detected above the normal. A purge was taken and all the symptoms subsided when the bowels acted freely. The patient then felt quite well, put on flesh, and had no trouble for a time. The attacks had become more frequent and more prolonged, but the intervals were still considerable. For example, the health was quite good from November, 1908, to March 10th, 1909, and the weight increased by six pounds. Then the last attack began, accompanied by diarrhœa, which was a new symptom. The patient had occasionally felt a lump in his side, but it could not be found by Dr. Mackintosh until March, 1909, when it was easily discovered in the region of the gall-bladder. It was then quite mobile, but when I saw the patient ten days later there was a swelling fixed in the cæcal region, apparently about 3½ inches in diameter and making the skin stand out quite an inch from the general surface of the abdomen. The mass was resonant on percussion, tense and elastic to touch, and hardly at all tender. The rest of the abdomen was soft and flat. The patient was pale, but his temperature was not raised; he was again gaining weight, and his bowels and digestion were acting normally.

The physical conditions seemed to indicate malignant disease. The history suggested that a more favourable cause of the mischief, such as a chronic appendicitis, might exist, and it was decided to explore the abdomen.

First operation.—The first operation was performed on April 3rd, 1909, when the swelling had considerably increased in size. An incision made over its most prominent part opened the peritoneal cavity and revealed omentum adherent to the abdominal wall and to the swelling. On separating this, 7 or 8 ounces of fœtid pus were released, but the peritoneal sac was not fouled by this fluid. To the outer side of the pus cavity there was a hard mass about 2 inches in diameter. The upper part of the incision was closed and the abscess was drained. The wound healed well except where the tubes were, and after two days the whole of the intestinal contents escaped through the drainage opening. The swelling gradually became smaller and its outer part was then more prominent.

It was obvious that there was an obstruction of the intestine between the fistula and the anus, and it was equally certain that this was caused by a new growth. The temperature fluctuated a good deal, rising at times to 102° F., and it was decided to short circuit the intestine before undertaking radical treatment.

Second operation.—On June 3rd, 1909, the abdomen was opened in the middle line, the small intestine was divided conveniently near to the cæcum, its upper end was inserted into the side of the sigmoid flexure, and its lower end was closed and fixed to the back of the median incision. The patient was very feeble at the end of this operation but gradually rallied. The new incision did not heal by first intention, but its union was not greatly delayed, and progress was otherwise satisfactory. Fairly regular evacuations of the bowels through the anastomosis and anus were soon established, fæcal discharge ceased, the skin around the fistula, which had been inflamed, became soft and fairly healthy, and the abscess contracted until it was a short sinus. The temperature fell to normal, but it always rose if the drainage-tube was displaced, and this frequently occurred, especially when the patient tried to move about more freely.

At the end of July it was decided that an attempt should be made to remove the new growth, and from a pathological point of view there should have been no delay, but it was thought wise to allow time for the inflammatory mischief to subside, as the mass seemed to become less fixed and it was anticipated that the operation would in any case be a difficult and severe one. The date first arranged was postponed because the patient developed an acute laryngitis, with a sharp rise of temperature.

Third operation.—On Oct. 19th, 1909, I excised the scar of the first incision and isolated the sinus, the cæcum was exposed, the omentum was detached from it, and the peritoneal cavity was freely opened. The piece of gut between the cæcum and the median incision was separated, and the cæcum, which was almost universally adherent, was enucleated from its adventitious and natural connexions and was brought outside the abdominal cavity. The ascending colon was divided well above the diseased parts and its end was inverted. One gland in the meso-cæcum was about three-quarters of an inch long but not hard. It was removed, but unfortunately was lost. No others were seen or felt. Many ligatures were applied to bleeding points and the incision was closed except where it was drained. At the end of the operation the patient was in a state of extreme feebleness, the pulse being hardly perceptible, and therefore no attempt was made to examine the anastomosis.

Recovery from the immediate effects of the operation was rapid under treatment by saline injections into the rectum, by warmth, and by strychnia. The pulse was beating 90 times to the minute within an hour. Some trouble from vomiting and intestinal distension gave rise to anxiety which ceased after the fourth day. Again the wound did not heal by first intention, but by the middle of December there was complete union except for a healthy sinus from which some ligatures subsequently escaped. Dr. Mackintosh extracted the last of these in February and then the wound finally healed.

At this time the patient could walk seven miles without

undue fatigue. There was some swelling of the right leg when it was first used, but this soon passed off. The patient's weight steadily increased, he felt better each day, and he required no medicine to aid the intestine.

Description of tumour.—Mr. S. G. Shattock has kindly described the specimen shown in the picture as follows: The cæcum is distended with a finely papillary tumour which has an extensive attachment to the wall and along one side has invaded the muscular coat. Reaching from the lowest part of the cæcum to the exterior there is a fistulous track, with the distal end of which a piece of skin is left connected.

Section through cæcum showing fistula at lower end, viewed from behind. The appendix and the distended portion of small intestine are not seen.

The small intestine is considerably enlarged near its termination by an extension of the tumour into it. The juncture of the ileum with the cæcum is recognisable externally by a deep constriction. The vermiform appendix is free from disease. A tube can be readily passed from it into the cæcum, but it has no direct connexion with the fistula before referred to.

Remarks.—Mr. Shattock suggested that the growth began as a non-malignant slowly-growing papilloma and afterwards became carcinomatous and grew rapidly. This offers an easy interpretation of the phenomena of the case with perhaps the exception of the cause of the abscess. It is probable that during six or seven years the symptoms were due to a simple intestinal obstruction, relieved by clearing the bowel, and it is not unlikely that the growth developed much earlier and caused no symptoms. This explanation may apply to other cases in which malignant disease of the intestine has been discovered after a prolonged history of illness. Recorded cases[1] also show that the swelling is sometimes so elusive that its existence might be doubted by the surgeon even after he had felt it. The parts may be so mobile that the tumour gets displaced under the ribs, into the pelvis, or behind coils of gut, and it may be thought that a mass of hard fæces had been felt.

That the abscess in the case now related formed rapidly just before I saw the patient is certain, because ten days earlier the tumour was moveable and in quite a different position. The absence of fever and of other evidences of inflammation was remarkable, but the possibility of this in connexion with peritoneal suppuration is too well recognised to create surprise. It is certain that in circumstances which are not well defined micro-organisms, which are perhaps not yet identified, exercise a pyogenic function without inducing evidences of fever.

These organisms may have escaped through the intestine or through the appendix. I think it most likely that they passed through the appendix and that the abscess was just about to burst into the bowel when I performed the first operation. That the appendix was not directly in contact with the sinus does not prove that this view is erroneous, for seven months passed between the evacuation of the abscess and the removal of the growth, and most appendix abscesses are completely healed six weeks after they are opened. The fistula in this case could not heal, and it naturally followed the straightest course from the cæcum to the skin. The appendix, with the rest of the cæcum, was almost completely shut in by adhesions.

The latest account (October, 1910) of this patient is that he is quite well, his weight varies very little, being 11 stones 1 pound. Before the first operation it was 9 stones, and between the second and third it was 7 stones. In 1906, when he suffered much from indigestion and was unable to take exercise, he weighed 13 stones 12 pounds. Now he is very active and recently walked from Brighton to Mortlake in one day.

TREATMENT OF A UTERINE FIBROID BY X RAYS.

BY AGNES F. SAVILL, M.A. ST. AND., M.D. GLASG., M.R.C.P. IREL.,
PHYSICIAN TO ST. JOHN'S HOSPITAL FOR SKIN DISEASES.

LAST year I published some preliminary notes on the treatment of a large uterine fibroid by Roentgen rays.[1] I shall now briefly recall these notes and describe the results of further treatment.

The patient, a single woman, aged 43 years, had been under the care of the late Dr. T. D. Savill for many years on and off for various nasal, gastric, and neurasthenic troubles. She had always suffered from vaso-motor symptoms of a peculiar nature, the pulse was always rapid (about 100), and she had frequent attacks of giddiness, flushing, abdominal swelling, and great prostration consequent on any gastric upset. In 1900 she had profuse hæmorrhage at the monthly periods, a symptom which led to the discovery that she had developed a fibroid tumour of the uterus. Between 1903 and 1905 the tumour grew very rapidly; between 1905 and 1908 she suffered from anæmia and various pressure symptoms, such as sciatica, and on one occasion she was laid up for some months with thrombosis of one leg. In 1903 the tumour could be felt extending up as far as three and a half inches above the symphysis pubis, with greater development on the left than on the right side. In 1903 the measurement at the level of the umbilicus was 30 inches, in 1905 it was 33 inches, and in 1908 it was 36 inches. Hæmorrhage continued to be severe; the patient was anæmic, and had to lead a very quiet life. She steadily refused operative treatment, and the mere suggestion that she should visit a surgeon caused her extreme distress. With a view to steady the nervous system galvanism was administered externally—a descending current to the spine, and also from the spine to the abdomen. She had several courses of this treatment, each course consisting of about 12 to 15 sittings, in the spring and autumn of 1906 to 1909. During and immediately after each course there was much pain at the menstrual period, and more flooding than was usual, but for several months afterwards there was no doubt in the patient's mind that she had less pain and flooding at the periods, and enjoyed better health. Thus, although she felt depressed during the time of treatment, she always returned to request another electrical course.

In May, 1909, the tumour was as high as the umbilicus, with a prolongation of about the size of a large fist extending upwards on the left side. The abdomen then measured 35 inches at the level of the umbilicus. As the patient still refused to see a surgeon I decided to commence treatment with the Roentgen rays, and tried first the method described

[1] Archives of the Röntgen Ray, August, 1909.

by Dr. Albers Schönberg.[2] During May and June, 1909, six exposures were given to each ovarian region. The tube was held at a distance of 38 centimetres from the surface of the body, and a filter was employed consisting of three layers of leather with two intervening sheets of tinfoil, in order to protect the skin by cutting off the soft rays. Altogether three Sabouraud pastille doses, measured 30 centimetres *above* the filter, were administered in 12 sittings. The menstrual period at the end of May was of customary amount, but in June it was very painful, and was preceded by intense discomfort and swelling of the abdomen, and there was more hæmorrhage than usual. The patient stated that the effect of the rays had been similar to that produced at the end of a course of galvanism, but much more severe. In July she had six more exposures. The tube was placed 15 centimetres from the body, and on an average ¾ of a Sabouraud dose (measured above the filter) was given at each exposure. At the end of July the period was accompanied by much pain and swelling of the abdomen, and the hæmorrhage was excessive. It appeared that up to that time the treatment had excited the ovarian function and upset the vaso-motor equilibrium. The patient felt so much mental depression that she refused to have any further treatment for a time. In August the menstrual period was again unusually profuse and painful, but in September the catamenia were slight and almost painless.

In October treatment was resumed, and Bordier's method was employed. In this method the pastille is placed on the skin, beneath the filter, and thus a truer estimate is obtained of the dose which, after passing through the filter, reaches the body than by those methods which measure the dose before the rays reach the filter. Three exposures are given each week by Bordier and each exposure is continued until the pastille acquires Bordier's Tint O. I followed his method as described in the *Archives of the Röntgen Ray* for December, 1909. I gave three exposures a week for three weeks, allowed a week or so to elapse, and then commenced again. I used as a filter a sheet of aluminium ½ millimetre thick. The patient would rarely allow me to give the correct dosage, and the dose at each exposure was therefore less than that prescribed by Bordier. During the sitting she complained of obscure, indescribable sensations, and as my tube worked slowly, taking over half an hour to turn the pastille, she frequently begged me to stop the treatment when only a half or three-quarter dose had been given. There is no doubt that in certain subjects the vaso-motor system is peculiarly sensitive to the static electricity surrounding an excited hard tube, sensitive in a manner never observed with the average individual. In this particular patient, on the afternoon or evening of the day of the sitting, there would often arise symptoms such as headache, mental depression, exhaustion, rapid pulse, and gnawing pain in the neck and ovarian regions.

With the above-mentioned limitations the Bordier method of treatment was administered 16 times between Oct. 5th and Dec. 4th, 1909. The effect of treatment is of interest. For two days preceding the October catamenia the abdomen was much distended, and on palpation I found the tumour was soft and enlarged. The upper part of the abdomen was also distended, but I was uncertain whether this was due to relaxation of the intestinal involuntary muscles or merely to the mechanical displacement upwards of the intestines by the enlarged tumour mass; the constipation present favoured a diagnosis of the former. There was certainly relaxation of the involuntary muscle fibre of the vascular system, the pulse being soft and rapid, as well as a generalised sensation of exhaustion and mental depression. The patient also stated that on some evenings she had swelling of one cheek, lasting several hours on each occasion; but this sign was never present when I saw her in the morning. During these attacks of abdominal swelling the only relief to the gnawing pain and general distress was obtained by a mixture of valerian, ammonia, and spirits of ether. After a slight oozing for a few days all the symptoms disappeared, the swelling decreased, and the tumour felt very hard to the touch, like the pregnant uterus during a "pain." A week later the swelling and general distress returned; the tumour was again large and soft to the touch. After four days the tumour contracted, and the patient felt well and bright for three weeks, except for occasional gnawing pain in the ovarian regions. Then the same symptoms returned with great severity, with nausea and intense mental depression. Slight oozing continued for a fortnight, a sign described by Bordier as having occurred in most of his successful cases after a few months' treatment.

Treatment was discontinued in the early part of December, and she had a profuse period at the end of that month. From the end of December to March 17th she had no hæmorrhage, but the abdomen began to swell towards the middle of February, and continued to do so until a protracted oozing began on March 17th. At the same time she suffered from intense mental depression—a symptom she had never known in her previous life. Mental and physical relief followed the flow at the end of March. When she was again seen by me, early in April, 1910, the measurements of the abdomen were as large as in May and June, 1909. Treatment was resumed on April 8th, 1910. The exposures were given with longer intervening intervals than in Bordier's method, sometimes as much as a week was allowed to elapse, sometimes only four or five days. When the patient complained of vaso-motor symptoms, headache, or abdominal swelling treatment was discontinued until she was better. Between April 8th and July 30th, 1910, she had in all 16 exposures, six over each ovarian region and four over the middle of the tumour. At each sitting the dose varied from ½ to 1 Tint O (Bordier). The history of the patient's condition was similar to that of the previous summer. The flow was absent or slight, with swollen abdomen and general malaise for a few days, followed by relief and contraction of the tumour after the flow ceased. In May and early July the flow was protracted, lasting for over a fortnight; on some days profuse, on most days merely an oozing. There was, however, no mental depression, and the patient felt more braced up than at any time during the previous year. She considered that her general health had improved and that she was less anæmic than of old. The attacks of abdominal swelling were not so marked; the tumour remained longer contracted, and in consequence the abdominal measurements were smaller in the intervals between the swellings than they had ever been in the previous summer.

Remarks.—Forty-four sittings have been administered to this fibroid during one year, but only on three occasions has a full dose been given. Bordier describes cases in which a tumour as high as the level of the umbilicus was reduced so greatly that it could be felt only by a vaginal examination, after a course of treatment extending over a year or a little longer. His cases had interstitial fibroids. During the time of treatment his patients exhibited flushing and other symptoms of the menopause, but in none does he mention such extremely severe subjective symptoms as occurred in my patient. It is to be noted that in my case the full dose was so rarely given that it may be reasonably considered that she only received about 20 doses in the 44 sittings. With so small an amount of X rays and with so large a tumour it could not be expected that as good results could be obtained as in the cases recorded by Bordier. Moreover, the prolongation on the upper left side of the tumour in my case points to the presence of more than interstitial fibroid growth. Considering the various drawbacks which made it impossible to carry out the treatment in its entirety, therefore, this case is more successful than it would at first sight appear. The patient is rid of the torture of a monthly or fortnightly flooding, even though the size of the tumour is but little reduced. As she is desirous of resuming treatment later, the final result may be successful.

I have thought it well to publish this at first sight somewhat unsatisfactory case for several reasons. So much interest has been aroused by the remarkable series of cases recorded by Bordier that I have received several letters of inquiry as to the further progress of this patient, the preliminary notes of which were published by request in the *Archives of the Röntgen Ray* last year. Most cases which have been published in full are successful cases; we do not have the records of the technique and signs of the cases which have been failures or only partial successes. There must be many who are working at this subject, and I trust that by writing this paper other British workers may be induced to describe their failures and successes, together with the technique of the treatment adopted in each case. Only thus can we find where our errors lie, which cases are likely to do well with X rays, which to do better with surgical operation. Undoubtedly there is danger in irradiating certain cases. The first effect of the rays is to excite further

[2] Ibid., May, 1909.

hæmorrhage, with consequent risk of life, and death has been reported to have followed in at least one case. Some time ago extirpation of the ovaries was a favourite method of treatment of uterine fibroid, and if we can work hand in hand with the gynæcological surgeon we shall know which cases should be dealt with by operation and which by irradiation of the ovaries.

Harley-street, W.

A CASE OF URÆMIA WITH FACIAL PARALYSIS AND INTESTINAL ULCERATION.

BY G. PARKER, M.A., M.D. CANTAB.,
PHYSICIAN TO THE GENERAL HOSPITAL, BRISTOL.

I DO not propose to discuss here the numerous complications of uræmia, but I shall confine myself to those met with in a single patient. The combination in one case of two such unlike things as facial paralysis and severe hæmorrhage from the bowel, and these almost the first symptoms brought to one's notice, well illustrates the difficulties we sometimes find in the diagnosis of kidney disease. The history of the present patient's illness is as follows.

A particularly vigorous, active nurse, aged 37 years, complained to me on Feb. 2nd, 1909, of facial neuralgia which had worried her for a fortnight. She was not anæmic and looked as usual in complete health. Menstruation commenced the same day and was normal. On the 3rd left facial paralysis came on and one eye could not be closed, but she went on with her duties as before. There was no ear trouble or history of sitting in a draught to account for it. However, the next morning she was attacked with slight vomiting and then passed from the bowel two or three pints of bright blood mingled with fæcal matter. It was difficult to see any connexion between the paralysis and the bleeding. There was no sign of purpura and the paralysis was of the ordinary peripheral type. The eye, by the way, could not be closed for a month afterwards. On the 7th menstruation ceased, but after a rectal injection profuse bleeding from the bowel again came on. I could find no polypus, piles, or other source of the hæmorrhage. Another severe attack took place next day, the 8th, after a vaginal and rectal examination by a gynæcologist, who could, however, find nothing amiss except a tender spot in the rectum some three inches from the anus. On the 10th the bleeding finally ceased under the use of adrenalin and other styptics. Vomiting was troublesome during the next week and a pyrexial condition for several days, with some convulsions, came on, but after that she made steady progress towards recovery.

I had noticed that the urine showed a cloud of albumin, but no casts, and it was of 1014 specific gravity. The heart was little if at all enlarged, but her previous history turned out to be important. As a child of 11 she had scarlet fever and diphtheria, and there had been some question of albuminuria afterwards. She had suffered from frequent headaches and nausea, though she was always active and able to work. When 25 she had a good deal of neuralgia and two years later gastric ulceration occurred and lasted on and off for five years. In August, 1908, severe headaches came on, but quieted down after a holiday. In November persistent vomiting in the early morning began and troubled her for some time, but did not interfere with her general health and activity.

A month after her extraordinary attack of facial paralysis and hæmorrhage violent headache and vomiting returned and lasted for some days. The blood pressure rose from 160 millimetres to 180 millimetres, the quantity of urine varied from normal to 100 ounces, and the cloud of albumin continued. No casts were ever found on repeated examinations, and no retinal changes were seen at any time. The anæmia following the hæmorrhage gradually passed away. In May another pyrexial attack appeared, with vomiting and most violent headache, which resisted all the usual treatment for uræmia until we tried venesection to the amount of 20 ounces from the arm, which gave immediate and most welcome relief.

Finally, in August there was a slight return of the bowel hæmorrhage, which was accompanied by considerable griping pain and mucous stools. Boric acid rectal injections increased the pain, but plain hot water ones soon gave relief. She has continued ever since in fair health, but with an increasing blood pressure, which at one time reached 220 millimetres, occasional rises of temperature and frequent headaches, especially if vaso-dilators are given to her.

It seems to me undeniable that we have here a case of contracting kidney which caused neuritic facial paralysis, hæmorrhage from the bowel, and ulceration, as shown by the dysenteric symptoms in August, but the combination of symptoms was most unusual and the activity and recuperative power of the patient are also remarkable.

Now peripheral facial paralysis generally follows a local chill or an ear trouble, and is rarely connected with any systemic disease except diphtheria or small-pox. It does, however, sometimes occur in uræmia, and besides the patient whose history I have given I have recently seen another young woman with chronic albuminuria and high tension pulse in whom this condition appeared for a time. Simpson long ago recorded instances in puerperal albuminuria. Uræmic cases are also mentioned by French writers, and Dr. J. Rose Bradford tells me that he has himself seen an instance without any obvious gross lesion post mortem. There are indeed in uræmic patients so many nervous affections commonly met with that it is curious that this particular form is not more frequently seen. It is difficult to say what is the pathology of this facial paralysis in uræmia, whether it is a toxic neuritis or due to a hæmorrhage or œdema in the sheath of the nerve. In the absence of direct observations we can only suppose that it is produced in the same ways as the ordinary form.

Intestinal hæmorrhage and ulceration have long been recognised as complications of Bright's disease, but well-marked instances are not very common. Of course, hæmorrhages occur commonly enough in kidney disease from other organs than the kidney. Too often they are cerebral, but ocular, nasal, and pulmonary ones are of daily occurrence. The cases of serious rectal hæmorrhage in uræmia which I can recall in my own practice have been in aged persons with probably degenerate vessels. Ulceration of the bowels is found post mortem more often perhaps than the text-books would lead us to suppose. Bright in his paper[1] noticed that among his 100 cases of albuminuria there were 19 in which ulceration of the intestine had taken place, and in 7 of these the large intestine was affected. Still he granted that some of them might be due to tuberculosis. Again, in 1859, Treitz described ulcers of the bowel in nephritis, due, as he thought, to the irritation from carbonate of ammonia excreted through the walls. Stengel favours the theory of the excretion of irritants as a factor at least in their production, since some enteritis is associated with them, but refers to three other explanations: (1) capillary thrombosis; (2) arterio-sclerosis of the local vessels; and (3) submucous hæmorrhages. He remarks, too, that several may coalesce, forming a large ulcerated surface.

Recent writers have confirmed the view that round ulcers of the stomach and duodenum are occasionally due to this uræmic condition. Dickinson[2] collected 22 cases of ulceration, of which 11 were in the small intestine only, 5 in the large bowel, and 2 in the stomach. He also recorded 8 cases of hæmorrhage without ulceration. In 9 of his 22 cases retinal changes were observed. Granular kidney was present in 14 cases, and a large white one in 2. He pointed out that the symptoms include griping pain, irritation of the bowels, and dysenteric diarrhœa, with the discharge of mucus in some cases, but there may be constipation and occasionally no bowel symptoms at all. Vomiting and hiccough too may be troublesome. The ulcers are commonly of regular outline, circular, and punched out, without any thickened edges. Perforation is common, and there are frequently hæmorrhages and ecchymoses in the neighbourhood. He took the view that the submucous hæmorrhage is the first step in the process of ulceration.

Matthieu and Roux found ulcers most often in young persons from the age of 18 to 25 years. A good account of a fatal case is given by L. G. J. Mackey of Birmingham.[3] The patient was a woman, aged 27 years, with profuse hæmorrhage from the bowel. There was a cloud of albumin in the urine and granular casts. Perforation took place a

[1] Guy's Hospital Reports, 1836, p. 385.
[2] Transactions of the Royal Medical and Chirurgical Society, vol. lxxvii.
[3] Brit. Med. Jour., April 24th, 1909.

week after admission. More than 100 small ulcers were found in the lower part of the small intestine and the cæcum, three of which had perforated. There were numerous submucous hæmorrhages in addition. He considers that the ulcers were due to the invasion of the hæmorrhagic areas by micro-organisms from the bowels. In another case which he mentions a leadworker, aged 28 years, died from cerebral hæmorrhage, but in the intestinal walls were numerous small hæmorrhages with commencing ulceration.

It is important to distinguish these cases from those of the so-called ulcerative colitis, to which Hawkins and others have lately drawn so much attention. In the latter there will be few, if any, signs of kidney disease, and there may be recurrent attacks for many years. Still, it is sometimes a difficult matter to decide which condition we have to deal with.

To conclude, ulceration of the bowel and hæmorrhage from it are important complications of Bright's disease and may lead to a fatal result. When a bowel hæmorrhage takes the place of a cerebral one the patient may have a better chance of recovery if he survives the immediate risks, but if it is due to extensive ulceration the condition is a very serious one.

Clifton, Bristol.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

HERNIA OF THE STOMACH INTO THE THORAX.

BY W. A. E. WALLER, M.R.C.S. ENG., L.R.C.P. LOND.,
HONORARY CONSULTING MEDICAL OFFICER TO THE ST. CROSS HOSPITAL, RUGBY

ON April 16th, 1910, I was summoned to see a young man, aged 20 years, one and a half miles from Rugby. On my arrival I found him dead. I was given the following history. On April 14th he was well and was spreading manure on a field. He ate a very hearty dinner (his father said he was usually a large feeder), including currant-roll pudding. In the afternoon he drove into Rugby with his father, but began to feel ill and vomited, but he walked part of the way home, carrying some fowls. He vomited several times during the evening and the night, and though he felt better on the morning of the 15th he lay about all day and took only milk and broth. He had an action of the bowels after taking salts. He slept well during the night of the 15th as far as his father (who slept in the next room) knew. At 8 A.M. on the 16th he had some hot milk, and later some coffee and brandy. At 9 A.M. the father went up to him and found him rather cold. At about 10 A.M. he died. On my arrival the only noticeable thing was the dark fluid (of the colour of bismuth stools) running from the nostrils.

On April 17th I made a post-mortem examination. More of the same coloured fluid was running from the nostrils. On opening the body there was apparently nothing wrong with any of the abdominal organs. On removing the chest-piece the right lung was found to be very voluminous, and the left cavity of the thorax was equally fully filled with something which was evidently not lung. Further investigation found the left lung to be of about the size of an average spleen quite compressed at the upper and inner side. The heart was firmly contracted and rather more towards the middle of the chest than usual. I then found that the whole of the stomach, except just the pyloric end, had passed through the œsophageal opening in the diaphragm into the left cavity of the thorax. There seemed to be no constriction, as the opening admitted three fingers easily. It contained a large quantity of the same blackish fluid mentioned as running from the nostrils, with the currants floating about, and other semi-digested food. The mucous membrane was deeply congested. The small intestines were mostly rather contracted, containing practically no fluid and only a little solid.

The parents did not send for help earlier because the son had a sick attack at Christmas which passed off in 24 hours. He had had no illness that I could hear of, but five years ago a heavy but empty farm cart passed over his left chest which necessitated a five weeks' stay in our hospital. I cannot hear that any definite lesion was discovered, but for several days he had an evening temperature of 101° F., and for several more only a degree less.

The patient was passed into a Foresters' Lodge a year or so after his accident, which I think could not have happened had the state of his chest been as I found it after death.

Rugby.

A CASE OF RICHTER'S HERNIA STRANGULATED IN THE OBTURATOR CANAL.

BY H. LEWIS BARKER, M.B., B.S. LOND., M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE SURGEON, ST. MARY'S HOSPITAL.

THE patient, a man aged 61 years, was sent up to St. Mary's Hospital on the night of Jan. 10th as a case of intestinal obstruction. He gave the following history. On the afternoon of Jan. 7th—that is, three days before admission—he was seized with sharp pain in the pit of the stomach. The pain was very sudden in its onset, but passed off to some extent so as to allow him to continue his business. He was not sick at the time. On the following day the pain was still present, but was of a gnawing character, and he had to discontinue his work. On the next day, the 9th, he was sick several times, and the vomited matter became brown in colour and offensive. His pain got easier towards night. On the morning of the 10th, before admission to hospital, he was given a rectal injection, but in spite of this his bowels were not open. He was sick about six times, and later his pain got much better. He said that he had always enjoyed good health previously to the present illness and that he was not constipated as a rule.

On admission his condition was as follows. He complained of slight gnawing pain in the abdomen. His countenance, however, was composed and cheerful. The temperature was 98° F. and the pulse was 88. The tongue was furred. The patient's abdomen was not appreciably distended and moved well on respiration. It was quite soft and there was no tenderness on palpation. The most prominent feature was the presence of visible peristalsis in the epigastrium from left to right. The patient being a thin man, this peristalsis was very obvious and striking. A rectal examination showed nothing abnormal to be felt in the pelvis. On the next day the abdomen was more distended, and besides the epigastric peristalsis there was also plainly seen peristalsis due to the small intestine, which made the abdomen assume a characteristic "grid-iron" appearance. There was no fulness in either flank. The patient was sick three or four times, the vomited matter still being brown in colour but not exceedingly offensive. An enema was given at night with a fairly good result. Until this time the bowels had not been open for six days. An analysis of the stomach contents showed that there was no free mineral acid. The total acidity was 0·07 per cent. There was no lactic acid and the ferment activity was low.

On Jan. 13th a laparotomy was performed by Mr. Clayton-Greene. An incision was made along the right linea semilunaris, commencing above the umbilicus. The pyloric region of the stomach was first explored and found to be normal; the rest of the stomach was also found to be normal. The cæcum was not distended. The small intestine, however, bulged into the wound and was distended and appreciably hypertrophied. The distended portion of small intestine was followed out and led to the left iliac fossa, when it was seen that a portion of the circumference of the gut was herniated into the left obturator foramen, and anchored there by recent adhesions. The hernia was reduced and the bowel washed with hot saline solution, when the intestine immediately showed signs of recovery. The peritoneal sac was drawn out of the foramen, but it was not possible to attempt a radical cure through the existing incision. In fact, during the operation the incision had to be enlarged till it was 8 inches in length, and even then it was difficult to manipulate the hernia, though a good view was obtained by turning up all the coils of intestine from the pelvis. The left obturator foramen was much larger than the right and admitted the tip of the finger. The efferent portion of small intestine was shrunk and perfectly empty. The incision was closed without drainage and healed perfectly.

The patient made an uneventful recovery and was discharged from the hospital on Feb. 10th. It is interesting t

record that he was again in hospital in April for a femoral hernia on the left side, for which a radical operation was performed, and he left the hospital cured at the end of the month. At the present time (October) the man is perfectly well and is able to take an active part in his business, which is that of a printer. I have to thank Mr. W. H. Clayton-Greene for permission to publish this case.

Remarks by Mr. CLAYTON-GREENE.—The special features in this case were: 1. The appearance presented by the patient of chronic obstruction in the small intestine. 2. Marked peristalsis of the stomach, suggesting a pyloric stenosis in addition to the blockage of the small gut. I was surprised to see gastric peristalsis so marked when the obstruction was so far from the pylorus. 3. The variety of the condition. Obturator hernia is so much commoner in women, in the proportion of 63 to 4 (Macready). Richter's variety of strangulated hernia is itself uncommon and the association of the two must be very unusual.

So far nothing has been done to prevent recurrence beyond reducing the sac by traction from the peritoneal cavity. The obturator opening on the left side easily admits the tip of the index finger, and it is reasonable to expect a recurrence of the condition. It seems feasible by making an incision parallel with and above Poupart's ligament to dissect down extraperitoneally to the obturator foramen and to block the opening with a flap of the obturator internus muscle.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Metal Drains in Chronic Abscess of Bone.

A MEETING of this society was held on Oct. 10th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Mr. SYMONDS delivered the presidential address on the Treatment of Chronic Abscess of Bone by means of Metal Drains. Before commencing his address he referred in sympathetic terms to the loss sustained by the society through the death of the late treasurer, Mr. J. Langton. The President then proceeded with his address and said that his object was to exhibit the results of treating the effect of central osteitis by metal drains. In some cases there had been a typical chronic abscess, in others the patients had shown a sinus leading into the centre of the bone. That sinus in some instances was the result of an acute or subacute osteitis occurring in early life, in others in adult life. Incidentally, it appeared that a greater number of the cases were the result of septic infection than was supposed to be the case. There was little or nothing in medical literature as to the after-treatment of these cases. The evacuation of an abscess by means of the trephine or gouge, or the enlarging of a bone sinus and the cleaning out of a central cavity were simple enough procedures and need not detain them. His concern was with the after-treatment, for in his own hands up to the employment of metal drains that stage was prolonged, unsatisfactory, and sometimes disastrous as regards the neighbouring joint. The wall of a chronic abscess of long standing was hard and smooth; there was, in other words, a barrier of dense bone. Unless that was removed by operation—an unwise proceeding—it took some time to undergo rarefaction by osteitis, during which time effective drainage was required to prevent decomposition. The difficulty in maintaining drainage was due to the closure of the orifice by periosteal growth. A metal drain prevented that and at the same time did not itself lead to irritation as did a rubber drain or a gauze packing. Those latter methods, especially in hospital patients, were notoriously difficult to maintain, and local septic infection almost always occurred. That led to a chronic osteitis, to the retention of pus from time to time with general septic infection, and almost always to secondary changes in the neighbouring joint. Again, for the process of recovery and for the closure of the cavity it was necessary that the enlarged bone be remodelled and restored to its normal size, a process taking under the most favourable conditions some months, and in others one or two years. The question he raised was what was the best method of dealing with a chronic bone abscess after the pus had been evacuated, or again of dealing with a case of acute or subacute central osteitis either immediately or if encountered some months or years after evacuation of the pus? With regard to chronic abscess, where the infective activity had long ceased and the pus acted more as a foreign body, the ideal method no doubt was to close the cavity after rendering it aseptic. The compact layer of bone that limited these old cavities had suggested to more than one worker the possibility of applying the method of dentistry, employing, however, an absorbable filling. Blood, bismuth, bone, and later a preparation containing iodoform in spermaceti had been employed. The difficulty of securing perfect asepsis was obvious. In the infective varieties where pus formed quickly—i.e., in a few days, or as in one instance three weeks—it was unlikely that an aseptic condition could be brought about. Nor would it be possible to remove all the septic products in those long-standing cases of sinuses with thickened bones. His own experience of attempts to close chronic abscess and of inserting periosteal flaps had not been successful, but he hoped that others might contribute some better experience of those methods of treatment. He must be content in putting before them a short summary of a method of drainage not much in vogue, though he thought by no means new, which had in his hands proved of the greatest value. Acting on the belief that there must be a discharge of pus until the enlarged bone had been restored by slow absorption and reconstruction to the normal size, a metal drain had been retained until that had taken place. It would be shown that a patient could carry on his work with a large drain in the femur or in the lower end of the tibia and that he could attend to the cleaning and management of the tube. Full use of the limb rather promoted than retarded recovery; the silver or aluminium gave rise to no irritation of the skin, and effectually prevented the retention and decomposition of pus and so the spread of osteitis and the slow general septic absorption which led to such depression of general health. The tubes had been made of silver, German silver, and aluminium. In the case of the last-named metal the flange must be riveted to the cannula. It would last a long time and was somewhat cheaper than silver, but was not quite so nice a material for the purpose. Lead in default of anything else would answer. The size should bear some proportion to the cavity. Theoretically it should equal the diameter, but that was unnecessary. In a large cavity a diameter of half an inch was sufficient. In the smaller cavities it was well that the diameter should be of a larger ratio to the cavity. After a year the tube could be reduced in size, the reduction depending upon the extent to which the bone had moulded down. Finally, a rod of metal having a flat nail head was worn for some time, or for cheapness a length of silver wire with the end turned over. The duration of drainage was also influenced by the localisation and the nature of the case. The duration of the drainage was, however, of less moment if the patient could go about his work and if the wound be kept free from septic changes. The age of the patient was also an important factor. From the pathological standpoint it would be noticed that nearly all the cases of Mr. Symonds were due to some form of acute or subacute infection. There were the cases of acute necrosis of early life, limited in some to one bone; in others several bones or other parts were involved; there were two cases of subacute infection, in both of which the lower third of the femur was the part affected, and in both there was a history of very slight injury. As to the cause of such cases one could in the absence of bacteriological evidence only speculate. Probably a staphylococcal infection might explain such cases or the bacteria of pneumonia or influenza. Those were interesting cases of multiple lesions in the same bone suggesting a widespread but attenuated infection, so mild that it might lie almost dormant for years, and give rise at intervals to local abscess over a period of 20 years or more. There were cases of long-standing sinuses with enlargement of the bone from a chronic septic osteitis and periosteitis associated in some with secondary joint changes, and all examples of acute disease in early life. In those perhaps one saw the most striking results from the metal drains. In regard to tuberculous cases Mr. Symonds had had several cases sent into hospital for tuberculosis appearing on a superficial examination to be of that nature, but which proved to be due to other causes. He thought in all probability a good many such conditions had

been set down to tubercle without sufficient evidence. The error was due, he thought, to the need of some other and reasonable explanation for the recurrence of abscesses and necrosis throughout a period of 10 or 20 years. Mr. Symonds suggested that those foci were all deposited during the initial attack of acute osteitis in early life and had remained more or less dormant. Those foci were never really quiescent, for a slow, painless osteitis associated with organisation was constantly going on. Some day the surface was reached and then there was pain. The protective layer of dense bone forming the wall of those old abscesses was the best evidence of chronicity.

Sir W. WATSON CHEYNE said that in dealing with septic cavities one method was to try to render the cavities aseptic, but his experience was that that was a very difficult thing to do. Another method which he recommended was to cut away as much bone as possible, so as to let the soft parts lie on the bottom of the cavity. If this procedure were not possible then recourse must be had to drainage, but there was a chance of the drain becoming plugged up and of further trouble ensuing. He was much impressed with Mr. Symonds's metal tubes, as the troubles with other methods of drainage were very great. Indiarubber drainage-tubes were of no use, as it was not possible to keep them in place, and if holes were made in them granulation tissue formed and blocked the orifices. If he (Sir Watson Cheyne) could not cut away and level down the bone as he had described, then he would certainly try the method shown them by Mr. Symonds.

Mr. A. E. BARKER said that they would be encouraged to persevere in the use of bismuth paste, which could reach the furthest ramifications in a bone cavity. The material appeared to act as a germicide and as a kind of framework for the growth of granulation tissue until the whole cavity became organised.

Mr. A. PEARCE GOULD said that the ideal treatment was by means of very patient and laborious operation to eradicate the whole of the affected area and flatten down if possible the dense wall of the abscess so as to secure a sound healing from the bottom, but if long drainage was required in any case then it appeared to him that the metal tubes used by Mr. Symonds would be most useful. He (Mr. Pearce Gould), however, hoped that the impression would not get abroad that in these cases it was sufficient treatment to drain by means of a metal tube for an indefinite time, because the great desideratum was eradication of the disease by a primary operation.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

Presidential Address.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Oct. 6th, Dr. F. HINDS of Worthing, the President, being in the chair.

The PRESIDENT delivered an address on Exophthalmic Goitre. He drew attention to the recent dictum of Professor Kocher, who stated that it was the duty of all practitioners to submit cases of this disease to operation at an early stage. The speaker contended that in order to make this a reasonable course of action it was necessary to regard Graves's disease as progressive, going on to the death or disablement of the subject of it. But was this the usual course of the disease? He believed not, and in support of this he drew attention to the after-history of 17 cases which he had watched for several years. Two were dead; both were women in whom the illness commenced about the menopause. In one valvular incompetence came on, followed by dropsy and death. The other died from acute mania. Of the others, one, an acute case in a young boy, was lost sight of, but a year after he was last seen he was said to be much improved. Another, still under observation, had mental symptoms from time to time, and insanity was feared. There were five young cases, all of whom had so far recovered as to be able to earn their living. Of the older cases, one, a man, completely recovered in about a year; the females were all well so far as heart symptoms went, and able to take their place in ordinary family life. One of them had an attack of mania, was in an asylum for about 18 months, but now showed no sign of Graves's disease. So far as these examples went he was entitled to say that they showed that a large majority of the cases of this disease got well spontaneously or as the result of medical treatment. He had never seen a necropsy on a patient dead from exophthalmic goitre, except as the result of an operation; with the exception of the patient mentioned, who died from heart disease, he had never signed a death certificate from this cause. As there was a considerable risk attaching to the operation, and as resulting improvement was by no means certain, were they justified in accepting Professor Kocher's ruling and submitting all cases to early operation?—In the discussion which followed all the members agreed with the view held by the President, and deprecated an early resort to surgery in the treatment of exophthalmic goitre.

The following cases and specimens were shown:—

Dr. W. WILLIAMS demonstrated the beneficial results of Mercurial Inunctions in a man with Localised Scleroderma. The patches were much softer after a course of these inunctions.

Dr. WALTER BROADBENT showed a case of Internal Hydrocephalus caused by cerebral tumour; trephining had been performed by Mr. H. H. Taylor, but no tumour found. For the last three months a needle had been inserted into the lateral ventricle through the trephine wound and two drachms of fluid let out every other day. Great improvement of the symptoms had resulted.

Dr. L. A. PARRY and Mr. W. B. PROWSE showed skiagrams of a child with Congenital Deformities of the Bones. There was shortening of the leg, due to want of development of the femur, with an absence of the upper two-thirds of the fibula. The latter, unlike the majority of these cases, had caused no club-foot.

Mr. PROWSE exhibited skiagrams of a patient with Congenital Lateral Deviation of the Fingers, with lax joints and webbing of the fingers.

Mr. GEORGE MORGAN showed a baby with Hernia of the Ovary. He had had six similar cases, and believed the organ was always cystic, and therefore should be removed at the time of operation. He also showed a Fibrous Nodule removed from the soft tissues of the thumb, which had caused very great pain. An X-ray photograph seemed to point to periosteum as the origin of the nodule. It was suggested that it might be a neuroma.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Oct. 7th, at which Dr. Leonard Williams, the new President, delivered an address on Some Further Aspects of Obesity. He said that recent investigations have served to throw a good deal of much-needed light on some of the intricacies of this rather difficult but ever-present question. Obesity has been defined as a "vice of metabolism," a definition which has the merit of being altogether indefinite and the disadvantage of committing the definer to nothing upon which he may be impaled. In ordinary obesity the vice is not in the metabolism, but in the metaboliser, who eats too much, drinks too much, excretes too little, takes no exercise, and wears flannel next his skin. When we come to the class which includes hereditary obesity, congenital obesity, asexual obesity, and the like, we are brought face to face with physiological problems of absorbing interest which, until they are solved, must always constitute corpulence one of the reproaches of the therapeutic art. The condition first described by Jonathan Hutchinson as lipomatosis universalis asexualis is clearly due to the absence or withdrawal from the economy of the internal secretions of the ovaries and testes. Both these extracts are believed on good experimental grounds to be anabolic—that is, to reduce or retard metabolism—and yet their complete withdrawal produces in either case so high a degree of anabolism as to be rightly regarded as pathological. The only two animal extracts which we know to be capable in certain circumstances of reducing corpulence are thyroid extract and pituitary extract. But in the case of the thyroid, while admitting to the full its katabolic power of stimulating certain forms of metabolism, it is certainly not imbued with that special hatred for fatty tissue with which it has been credited. Many patients who have been benefited by thyroid extract have really been suffering from myxœdema due to a minor degree of thyroid inadequacy. Pituitary insufficiency may give rise to a state of pseudo-obesity resembling that arising out of inadequacy of the thyroid. Obesity is often associated with chlorosis, and this form is related to, though it is probably not identical with, the type of obesity which is so liable in the female sex to occur at puberty, in connexion with marriage, and after maternity, and is consequently due to some internal secretory cause. In the case of maternity the cause may be the internal secretion

of the mammæ, which is believed by some to be very active. In connexion with marriage Mr. Arbuthnot Lane holds the view that the prostatic fluid of man is essential to the full normal physiological development of woman, to point to an explanation of post-marital obesity, which is by no means unlikely to be correct.

NEWCASTLE-ON-TYNE CLINICAL SOCIETY.—This society commenced the work of the winter session on Oct. 6th, meeting in the Geographical Institute. The business of the meeting was the installation in the chair of the President-elect, Dr. E. Napier Burnett, by the retiring President, Mr. J. W. Leech, who in well-chosen sentences formally introduced Dr. Burnett to the society. Dr. Burnett then took the chair and delivered the Presidential address on "Obstetrics in Relation to Some of the Allied Sciences." The lecturer gave some introductory remarks, pointing out the various ranges of normality in analyses of the urine from the standpoint of the nitrogen excreted in relation to the food intake in healthy individuals. He then proceeded to discuss quantitative and qualitative changes in the nitrogenous excretion of pregnancy. He pointed out that there were few cases in which the urine remained normal in this particular, and outlined the symptoms shown by patients of various types through a slight qualitative change, and through what he described as a pre-eclamptic change, up to extreme cases of eclampsia. He urged the necessity of medical men making something more than a mere cursory examination of the urine at odd times in pregnancy, and being content if there were no albumin present. He pointed to the need for eliminative treatment in the pre-eclamptic phases, and sketched a parallel between such cases and acetonæmias and subacute degenerations of the liver. The address was full of suggestive ideas and was received with enthusiasm.

Reviews and Notices of Books.

A System of Medicine, by Eminent Authorities in Great Britain, the United States, and the Continent. Edited by WILLIAM OSLER, M.D. Oxon., F.R.S., Regius Professor of Medicine in the University of Oxford; assisted by THOMAS MCCRAE, M.D., F.R.C.P. Lond., Associate Professor of Medicine and Clinical Therapeutics in the Johns Hopkins University, Baltimore. Vol. VII.: Diseases of the Nervous System. The Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 969. Price 30*s.* net per volume, or 24*s.* net per volume to subscribers.

WITH this, the seventh, volume the System of Medicine of Professor Osler and Dr. McCrae is completed, and the editors are to be congratulated on rounding off their arduous task with so excellent a production. The specialty of neurology has now become so large that it is no easy matter to compress into less than a thousand pages a series of authoritative articles by American and English experts on the multitudinous diseases to which the nervous system is subject. The contributors have, without exception, exercised a most praiseworthy self-denial in their determination to attain conciseness, for, as all who are familiar with neurology are aware, there are so many affections in regard to whose nature and pathology finality has not been reached that it is difficult to give an adequate account of them without alluding to various opinions in detail, and this inevitably lengthens the descriptions. The general impression we get from a perusal of this seventh volume is that it supplies an admirable account, alike in compactness and completeness, of present-day knowledge of nervous disease. Where all is so good it is perhaps invidious to single out any contributions in particular, but we should like to refer especially to the scholarly chapter on apoplexy from the pen of Dr. Henry M. Thomas, and to Dr. Smith Ely Jelliffe's critical study of hysteria.

The classification that has been adopted is on somewhat original lines. An attempt has been made to include as much as possible in such comprehensive subdivisions as "diseases of the motor tracts," "scleroses of the brain," "diseases of the meninges," "diffuse and focal diseases of the spinal cord," "combined system diseases of the spinal cord," "diseases of the peripheral nerves," and so on, but while the method has much to commend it, it may give rise to an erroneous conception of the degree to which systematisation of neurological knowledge has progressed. Thus, under the first of these, diseases of the motor tracts, we find described peroneal muscular atrophy, in which condition the posterior columns, not to mention other non-motor structures, are constantly affected, and, more curious still, the progressive hypertrophic interstitial neuritis of Dejerine and Sottas, in which disease the lesions of the cord are similar to those of tabes, while the changes in the nerves are just as marked in sensory as in motor fibres. It is unfortunately the case that the nature of not a few nervous affections is still undetermined, and therefore premature systematisation is to be deprecated.

The most recent advances in neurological science—we may mention, for instance, those in connexion with the subjects of acute poliomyelitis and serous meningitis—have all been incorporated, and throughout there is a refreshing novelty in the way in which the matter is presented to the reader. This effect may in particular be produced upon the English reader and be due to the *personnel* of the contributors, 13 out of the 16 whose names appear at the head of articles belonging to the United States and Canada; in any case the value of this treatise, to the comprehensiveness of which allusion has already been made, is increased by the bright and interesting manner in which the subjects are handled. The paragraphs devoted to a historical summary of the various diseases dealt with are often very instructive. An excellent index is given at the end of the book, as well as a general index to the whole seven volumes.

We have no hesitation in saying that the seventh volume of the "System" is a credit to English and American neurology, and anyone who desires a succinct yet detailed account of nervous disease will find it here, together with adequate appreciation of, and reference to, the work of other authorities.

Medical Examination of Schools and Scholars. Edited by T. N. KELYNACK, M.D. Vict. London: P. S. King and Son. 1910. Pp. 434. Price 10*s.* 6*d.* net.

THIS book is made up of a series of chapters by different authorities on almost all aspects of school medical work. Not the elementary schools alone, but the secondary and public schools are touched upon, and there are chapters also upon medical examination in the schools of Australia, Canada, and New Zealand, America, France, Germany, Switzerland, and Scandinavia.

An even cursory reading of this volume should enable anyone to see at once the weak and the strong points of the present system; while for those who wish to get a grip of practical methods for working purposes some of the articles are admirable. For this latter purpose the second chapter on the Organisation and Administration of the Medical Examination of Schools, by Dr. George Reid and Mr. J. Priestley, and the third chapter on the Organisation and Administration of the Medical Examination of Scholars, by Dr. W. J. Howarth, are both good and useful, and should give anyone coming new to the work a sound knowledge of what is expected and what is desirable. On this subject, however, Dr. Clive Riviere's article on the General Routine Medical Examination of School Children is particularly excellent and will be recognised by anyone with any experience in such examinations as embodying just those principles which assure smooth working and efficiency. Dr. Clive Riviere's observations on the heart of the school child will be most valuable to school medical officers as the conditions found are apt to be very perplexing, and his

hint as to the avoidance of strain is suggestive. We think it, however, possible that a good many of the heart conditions found in elementary school children may be themselves signs of some degree of chronic malnutrition, which affects a considerable proportion of children in the poorer quarters of large towns. Finally come the statements that "a pleasant relationship to child, teacher, and parent is essential to the success of the school doctor. He is placed in the school not only to collect facts, not solely to learn, but also to teach and advise" the teacher, the parent, and the child, the former "in the application of the laws of health," and the latter "in the value of personal hygiene"; and these might well form part of the preliminary instructions sent to every school medical officer on first beginning work.

The weak points of the system of medical inspection are made clear in several chapters. The first, which deals with the Correlation of the School Medical Service and the Public Health Service, by Dr. Edward W. Hope, does little more than make this weak point obvious, as the author does not suggest anything except the desirability of coöperation, and brings forward no definite suggestion as to how this coöperation is to be attained. In Chapter IV. Dr. Clement Dukes draws attention to one of the anomalies of our educational system, the fact that masters in public schools have very usually no training in teaching and no knowledge of hygiene. It is curious to think that our free elementary schools will soon be better equipped in these ways than our most expensive public schools.

Among other weak places in our system are the schools for mental defectives, who are given an elaborate and expensive education up to the age of 16 and then turned adrift on the world for whose struggle they are unfitted. As Mr. A. F. Tredgold says, this course of conduct can only be regarded as "the height of folly." Another serious defect in the general system is revealed in the case of Poor-law, orphanage, and reformatory schools. These institutions seem to be quite inadequately inspected—a very serious condition that should be promptly remedied. One chapter is missing that we should have liked to see—that on the school treatment of epileptics. This particular class at present, it seems, is left to take its chance without any special institution to help it. Other useful articles in the book are that by Mr. George Foggin on the Eye and Eyesight of School Children, that by Dr. Lewis Williams on School Clinics, and that by Dr. J. Lambert on Feeding the School Child. The examination of ears and hearing proposed by Mr. Arthur H. Cheatle seems to us over-elaborate if proposed to be done in the schools, although excellent if proposed to be done at some special centre by the expert, after the school medical officer has done the usual routine examination.

The establishment of school clinics as outlined by Dr. Williams would, among other desirable things, provide us with a centre at which all kinds of special and detailed examinations could be carried out. School clinics have been already established at Bradford, Bow, Brighton, Cambridge (teeth only), Sheffield, and Southampton. We are not told much about the clinics except in the case of Bradford, which treats ringworm, impetigo, scabies, ear discharge, dirty and sore heads, defective vision, and sore eyes. Probably all clinics will have to treat a good deal of this kind of ailment, and it is certainly not a field in which there will be, for the poor class of children treated, much possibility of interference with the work of the general practitioner. Nevertheless, the treatment of these conditions in school clinics should make a great difference in the level of school health, and the same may be said for another department of the work, the use of the clinic for purposes of diagnosis in doubtful cases and the certifying of children recovered from zymotic diseases as free or otherwise from infection. Dr. Williams makes an interesting suggestion of the possibility of "flying clinics" visiting country districts.

Altogether the "Medical Examination of Schools and Scholars" will be found full of suggestion and of interest.

Tropical Medicine and Hygiene. By C. W. DANIELS, M.B. Cantab., M.R.C.P. Lond. With a chapter on Snakes, by A. ALCOCK, C.I.E., M.B. Aberd., F.R.S., Lieutenant-Colonel, I.M.S. In three parts, with coloured and other illustrations. Part II.: Diseases due to the Metazoa. London: John Bale, Sons, and Danielsson, Limited. 1910. Pp. 233. Price 7*s.* 6*d.* net.

WE had the pleasure of reviewing the first part of this treatise, which deals with the protozoa in connexion with tropical diseases, in THE LANCET of June 25th, 1910, p. 1762. The present volume deals with those due to the metazoa. Lieutenant Colonel Alcock has added a chapter dealing with snakes. Major E. Wilkinson, I.M.S., who was responsible for part of the subjects contained in the first volume, has been precluded from any share in the work under review owing to his absence from the country.

In this, as in the former volume, we find a concise description of the diseases due to various kinds of parasites, of the manner in which they spread, and the rationale of the preventive measures advocated. After an introduction, in which the etiological relation of the metazoa to disease is briefly indicated, the platyhelminths are first considered. This class comprises the turbellaria, the trematoda or flukes, and the cestoda or tape worms. Their anatomy, illustrated by some excellent plates, is succinctly given. In the remarks on bilharziosis we note that as regards treatment the author has not found any benefit from the administration of methylene blue, a drug recommended by Lieutenant P. S. Lelean, R.A.M.C., in 1902. Dr. Daniels not only considers it useless, but harmful, as it may cause renal trouble. With respect to the question as to whether or not there are two species of parasite included under the description of the worm responsible for the disease, the author holds that the balance of opinion is in favour of a second species. The chapter on tapeworms is excellent; we note especially the excellent plates with which it is illustrated.

The nemathelminths are next considered; these include the nematodes, nematamorpha, and the acanthocephala. The diseases for which the nematodes are responsible include the various forms of filariasis; here the student will find all the main facts relating to chyluria and elephantiasis; the treatment advocated is quite up to date. The author considers the method of lymphatic drainage by strands of silk, so as to establish passages in the subcutaneous tissues, connecting one lymphatic system with another, of some promise. Castellani's practice of combining the removal of longitudinal wedges of skin with the use of fibrolysin is held not to admit of any definite opinion as to its value, owing to the want of sufficient experience. An excellent table is given of the differential characteristics of the various forms of filaria. In the treatment of guinea worm the author considers the methods of dropping cold water on to the part affected, of extraction by gradually withdrawing the worm on a piece of wood, and the method of injecting perchloride of mercury. A modification of this has very recently been advocated by Lieutenant H. W. Acton, I.M.S., who has employed the subcutaneous injection of chinosol with success in 18 cases out of 19, the disadvantage of the perchloride being the formation of an insoluble mercury albuminate on contact with the tissues. In the etiology of guinea worm Leiper's researches are noted. Trichinosis is duly considered; in the prophylaxis of the disease due stress is laid on the importance of thorough inspection of pork

before it is issued for consumption. In this connexion the admirable practice in vogue in Berlin occurs to the mind, where, when the pigs are killed and the bodies scalded, sections are at once made and examined microscopically at a large central institute. The subject of ankylostomiasis follows. Its symptoms, the characteristics of the ova, the prognosis, morbid anatomy, and the treatment are fully shown, and the cautions with reference to the use of thymol are not forgotten. The researches of Looss as to the mode of entry of the worm into the human organisms are related, whilst due stress is laid on the necessity of prophylaxis.

After the ascaridæ have been considered the author gives some useful diagnostic criteria of the various entozoal infections, with a plate illustrative of the different ova, the respected measurements of which are tabulated for comparison. A *résumé* of the prophylactic methods necessary against the various parasites that have been described next appears, and it is pointed out that in considering prevention of parasitic infections we have to take into account the following incidents in their life-histories: (1) how the parasites, eggs, embryos, or larvæ leave their host (man); (2) what happens to them afterwards; and (3) how they re-enter their host (man). This chapter is one of the most valuable in the book. Dr. Daniels concludes his work with an account of the morbid effects due to leeches, arthropods, and diptera, whilst myiasis, nasal, intestinal, and dermal, is fully discussed.

We then come upon a feature that has hitherto been wanting in treatises on tropical medicine. This has been supplied by Lieutenant-Colonel Alcock in the chapter on snakes and snake venom. In this he describes the general zoological characters and classification of snakes; the venom apparatus and venom of the thanatophidia; the treatment of snake-bite in theory and practice; and, lastly, the genera and species of venomous snakes and their geographical distribution. A vast amount of useful information is condensed in this chapter, which should be most valuable to medical men in India, contributed, as it is, by an officer of the Indian Medical Service who is so well known for his scientific work. Altogether the present volume fully sustains the reputation of its predecessor in every way.

Die Individualisierende Operation der Inveterirten Scheiden-Damm-Mastdarm-Risse (*The Individualisation of Operations for Tear of the Pelvic Floor.*) Von OTTO KÜSTNER. Mit 7 Tafeln und 10 Abbildungen. Jena: G. Fischer. 1909. Pp. 36. Price 3.50 marks.

THE multiplicity of the operations for the repair of tears of the pelvic floor is well known and is exemplified in some of the more modern American text-books, in which not uncommonly large numbers of them are described. Every gynæcologist who meets with many of these cases has his favourite method of procedure, and the principles upon which they are based are equally numerous. Nor is this surprising when we remember the great differences of opinion which exist even among anatomists as to the relative value in supporting the pelvic viscera of the different structures forming the pelvic floor. Professor Otto Küstner is no exception to the rule, and in this work lays down very clearly and dogmatically what he conceives to be the best method of dealing with these cases. The book is illustrated by some simple diagrams and a number of stereoscopic photographs, so that the description in the text is easily followed. As is almost invariable, the author condemns most operations but his own, and is very severe upon the time-honoured flap-splitting method of Lawson Tait—an operation which we must confess we favour, and from which we have seen very excellent results ensue.

Professor Küstner points out the well-recognised fact that practically every tear of the perineum takes place to one or other side of the middle line, and he further points out that as the tear heals with the formation of scar tissue the two halves often become markedly displaced and the anatomical relations distorted by the shrinking of the scar tissue. Since the amount of tearing and distortion of the two sides is very unequal, all the ordinary methods of suture, according to the author, fail, as they take no notice of this inequality, and therefore any raw surface if formed symmetrically may result in the removal of too much tissue on the one side and of too little on the other. For this reason he maintains that every injury must be treated on distinct lines of its own, and the first essential is to remove all the scar tissue and to restore the condition of things to that present at the time of the tear, before healing and disfiguration by the formation of scar tissue took place. The original wound in this way having been reproduced perfectly, the corresponding portions of the torn tissues must then be carefully defined, and if necessary isolated—for example, the sphincter ani muscle—and sutured accurately together. In this way alone is it possible to replace the parts in their original anatomical relations and completely to restore their functions.

It is important to bear in mind that after a perineorrhaphy the patient is very likely to bear further children, and the endeavour of the surgeon should be directed to forming a perineum which will stand the test of childbirth without necessarily giving way again. Full details of the special technique employed by the author are given, and by his method he maintains that the worst lacerations can be made to heal without any trouble; at least, so an experience of 20 years has taught him. Undoubtedly, the method has given good results in Professor Küstner's own hands, and the perusal of this clearly written and excellent little monograph should allow others to practise this procedure with a good measure of success.

Operations upon the Uterus, Perineum, and Round Ligaments. By W. J. STEWART MCKAY, M.B., M.Ch., B.Sc. Syd., Senior Surgeon, Lewisham Hospital for Women and Children, Sydney. With 148 plates. London: Baillière, Tindall, and Cox. 1909. Pp. xvii.–454. Price 21*s.* net

THE author has written this book with the object of pointing out how the obstetrician should deal with immediate lesions of the vagina and perineum, and, in the next place, to describe how these lesions when neglected may be dealt with later by the operator, whether he is a general practitioner or specialist. He thinks that the old idea that the perineum is a keystone and the supporting structure of the vagina and uterus is still firmly rooted in the minds of a great many members of the profession. We hardly think the present-day practitioners, at any rate those who are in the habit of performing gynæcological operations, are so ignorant as the author imagines, but it is with this idea in his mind that he has written this work of some 454 pages, mainly on operations for lesions of the perineum and for the various conditions, such as cystocele and rectocele, commonly associated with prolapse. It is true that 110 pages are given up to a consideration of the operation of curettage, which no doubt is somewhat abused at the present day, but the practical abuse of this simple and undoubtedly useful operation is certainly more than equalled by the author's abuse of his reader's patience. We are glad to remember that the majority of writers on gynæcology can discuss curettage fairly fully in less than 110 pages.

The author in his excellent account of the anatomy of the pelvic floor and genitalia describes the levator ani muscle as arising from the white line, and the fourchette as often formed by the posterior extremities of the labia majora. We believe that in neither of these descriptions is he correct, and he is certainly in disagreement with the majority of good

anatomists. The various operations which can be performed upon the pelvic floor are described well and in great detail, and the illustrations, of which there are a very large number, are extremely good. The account given of the action of the various portions of the pelvic floor is also good. The author strongly condemns the operation of ventrofixation in patients likely to become pregnant, and maintains that it is almost a surgical axiom that this operation should never be performed upon a patient in such conditions. We are of opinion that the manner in which the operation is performed is an important factor in these cases, but the contention of the author is a sound one. Dr. Stewart McKay's methods do not err for want of thoroughness; thus we note that in cases of well-marked prolapse he curettes the uterus, amputates the cervix, performs an anterior and posterior colporrhaphy, removes piles, and finishes the operation by performing ventrofixation. Certainly any surgeon who desires information on the various methods of treating displacements of the uterus by operation might do worse than read this book, and although in our opinion the article on curettage is of inordinate length and quite out of relation to the importance of the operation, yet it certainly does contain a great deal of useful information and will prove helpful to anyone who can afford the time to read it. If we may judge from the last chapter—on dysmenorrhœa—which appears to be interpolated for the purpose of describing Dudley's operation of incising the posterior lip of the cervix, the author in young women who suffer from dysmenorrhœa performs Alexander's operation when "between the times of the periods they suffer from constant backache." We cannot imagine a more unnecessary procedure or a statement more likely to do harm when read by anyone not able to appreciate such treatment at its correct value.

History of Medicine. By Dr. MAX NEUBURGER. Translated by ERNEST PLAYFAIR, M.B. Lond., M.R.C.P. Lond. In two volumes. Vol. I. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 404.

THE volume of the translation of Dr. Neuburger's "History of Medicine" now before us includes Vol. I. and Part 1 of Vol. II. of the original German edition. Part 2 is in course of publication and will form Vol. II. of the English translation. We have already reviewed the book in its German form[1] and can only express our pleasure that such an excellent work should have been made accessible to readers who have no knowledge of German.

A good history of medicine in English has for long been a desideratum. Freind's work is, of course, a classic, but much both in ancient and modern medicine has been discovered since his day, and Dr. Withington's book, admirable though it is, of necessity treats the subjects in a superficial manner, owing to its small size. All the same, it is of great value to the student of medical history as a bibliography and record of authorities who may be consulted for further information. Dr. Neuburger's work being planned on a larger scale than that of Dr. Withington, has enabled its learned author to treat the subject matter more at length. His style is simple and easy, and Dr. Playfair has succeeded in producing an eminently readable translation. The volume before us contains the history of medicine from the earliest (Neolithic) times down to the thirteenth century, while the influence of Arab medicine on Western Europe is reserved for the next volume. And no one who reads the first volume will fail to look forward with interest and expectation to the appearance of the second.

[1] THE LANCET, June 8th, 1907, p. 1575, and June 25th, 1910.

LIBRARY TABLE.

The Prevention and Treatment of Abortion. By FREDERICK J. TAUSSIG, A.B., M.D., Lecturer in Gynæcology, Medical Department, Washington University. With 59 illustrations. London: George Keener and Co. 1910. Pp. 180. Price 9*s.* net.—The treatment of cases of abortion is undoubtedly a very important part of the work of a medical practitioner. Whether the subject is so important as to merit a book being devoted to it alone is a matter of opinion, but apparently Dr. Taussig considers that it is. He certainly makes out a very strong case for his contention when he tells us that he finds the ratio of abortions to confinements among 600 gynæcological patients as high as 1 to 2·3, a proportion a good deal higher than that usually given by most authors, namely, 1 to 5. Criminal abortions, he states, are also very frequent; thus he found them in no less than 10 per cent. of his own cases, while Treub finds 52 in 218 abortions, or a percentage of 25. Not only are abortions relatively commoner than we usually imagine, but the death-rate is also high, at any rate when septic infection is present. Dr. Taussig quotes Sittnev as recording among 267 uncomplicated cases one death only, but no less than three deaths among 35 septic cases. Maygrier's figures are even more striking, for while the mortality of his spontaneous abortions was 0·57 per cent., that of his criminal abortions was no less than 56·8 per cent.; and it must be remembered that these figures take no account of the excessive morbidity rate attending such cases. The large part which criminal abortion must play in the production of gynæcological affections is shown by the figures quoted by the author, showing that 80,000 criminal abortions occur every year in New York and from 6000 to 10,000 a year in Chicago. There does not seem much hope that this crime will diminish in frequency; rather is there evidence to show that it is becoming more and more prevalent in all the cities of the world. The author trusts that education and legislation may have some effect in diminishing the practice; but although severe penalties are enforced by the laws of nearly all countries, only too often they are a dead letter, and the difficulties of obtaining a conviction in these cases are notorious. We notice in the treatment of cases of retroflexion and pregnancy that the author favours the introduction into the vagina of a colpeurynter filled with mercury. For our part we prefer the method of exerting pressure upon the uterus, a very efficient method, by means of a rubber ring of large size. The treatment of abortion as laid down by Dr. Taussig is eminently sound. He rightly deprecates undue interference in cases of uncomplicated abortions and summarises the operative indications thus: "In the absence of immediate danger await developments, and operate only when complications arise." In describing the method of evacuating the uterus in cases of incomplete abortion the author does not lay enough stress upon the importance, indeed the absolute necessity, for getting the uterus anteflexed and held by the left hand against the back of the symphysis pubis before any attempt is made to introduce the finger into its interior. In this way alone is it possible to carry out properly his advice to push the uterus down on to the finger and not to attempt to push the finger into the uterus. Indeed, except in very early cases of pregnancy unless this manœuvre is carried out there will be the greatest possible difficulty in reaching the fundus uteri. With the principles of treatment as recommended by Dr. Taussig we are in complete agreement, and this monograph he has written is a very good one and will repay perusal even by the specialist.

Hints for the General Practitioner in Rhinology and Laryngology. By Dr. JOHANN FEIN, Privat-docent in the University of Vienna. Translated by J. BOWRING HORGAN. London:

Rebman, Limited. 1910. Pp. 223. Price 5*s.* net.—As an easy mode of access to the subjects with which it deals, this book leaves little to be desired. It is written in a pleasant and readable manner, for which the translator deserves some of the credit, and it exercises little or no strain upon our powers of comprehension. It might be said, indeed, with some truth, that Dr. Fein places the general practitioner's attainments at too low a level, as, for instance, when he includes "ozæna" among "diseases of the nose the recognition and treatment of which is [*sic*] only possible for one who has had some special training." With regard to the suitability of the book as a guide to British practitioners its value is impaired by its having been written for a foreign people whose customs are different from ours. We should not at all satisfy the public in our country, for example, if we were to operate on tonsils and adenoids without an anæsthetic. Dr. Fein's teaching in general runs along familiar lines, but he is singular in recommending that after turbinotomy "the nose should remain plugged for from one to four days." This is advice which, we are sure, nearly all modern rhinologists would deprecate.

Science and Singing. By ERNEST G. WHITE. London: The Vincent Musical Co., Limited. 1909. Pp. 72. Price 4*s.* 6*d.* net, or $1.25 net.—The author of this brochure has discovered that tone is produced in the nasal accessory sinuses, the higher notes in the frontal sinuses, the middle in the ethmoidal cells, and the deeper in the sphenoidal sinuses. The function of the vocal cords is merely to direct the current of air, like water from a hose-pipe, into these various chambers, from which it sweeps out the mucus like a broom in a spring-cleaning. (The metaphors are the author's.) He has also discovered, and a photograph of a dry skull is reproduced to prove it, that the bony palate is filled with "hundreds of air-cells." Armed with his theory, the author marches forth conquering and to conquer—deaf-mutism among other things; "such an individual as a deaf-and-dumb person will not be known throughout the length and breadth of the civilised world." Curiously enough, it has had a different effect upon us. It has rendered us speechless.

INTERNATIONAL HYGIENIC EXHIBITION, BUENOS AIRES, 1910.—A grand prize has been conferred upon Messrs. Burroughs, Wellcome and Co. for their exhibit at the International Hygienic Exhibition now being held in Buenos Aires.

THE GUILD OF BRAVE POOR THINGS.—Princess Louise, Duchess of Argyll, has sent us a letter of appeal on behalf of the Heritage School of Arts and Crafts for Crippled Boys at Chailey, Sussex, which is in connexion with the Guild of Brave Poor Things. The object of this school is to inspire the children with courage to fight against their handicap in the battle of life and to equip them to support themselves by a thorough training in suitable crafts. Hitherto the work has been carried on in a temporary building, but now, when the full value of the teaching given to the children has been recognised by the Board of Education and the school is full to overflowing, with a long waiting list, it has become absolutely necessary to make the buildings suitable for modern requirements. The necessary alterations and extensions will cost about £5000, and towards this sum a few friends have promised or guaranteed £2500 conditionally on a sufficient sum being raised. Princess Louise feels sure that the crisis has only to be made known to bring forward other helpers. The girls' school is a new building the gift of Lord Llangattock. It is of melancholy interest to note that it is proposed to name the new gymnasium for the school after the late Hon. C. S. Rolls, who took a keen interest in this branch of the Guild's work, and on account of whose lamentable death at Bournemouth the speech day of the school which was to have been held on July 23rd was cancelled. The president of these schools is the Bishop of London, and the honorary treasurers Lord Llangattock and Miss Alice Rennie, 36, Westbourne-terrace, Hyde Park, W., who will be happy to receive contributions.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

"TABLOID" BISMUTH GAUZE.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

THIS is a new antiseptic dressing which will be appreciated for several reasons. The antiseptic is a bland bismuth compound which is non-toxic and without odour. The gauze readily responds to the test for bismuth. The gauze can be used in all cases in which iodoform gauze is employed, but it has the demonstrable advantage that when used as an absorbent dressing in the uterine cavity it remains odourless for five days, while in the same situation iodoform gauze becomes offensive in 48 hours. It clearly offers a powerful yet non-irritating antiseptic surface which will be found convenient and effective in gynæcological practice. The gauze is made in widths of 1, 2, and 3 inches, and is carefully sterilised and packed in one-yard rolls which are surrounded by a specially varnished germ-proof cover.

PRESERVED MANGO JUICE.

(THE ORIENTAL CANNERY CO., HONAVAR, INDIA.)

We found that the process of preservation of this juice is free from objection; there were no undesirable preservatives present, the pulp was in good condition and sound, while the inside of the tin was bright and clean. The juice had the peculiar taste of the fresh mango, a fruit which is much esteemed in India and in America. The mango tree is peculiarly sensitive to frost, and therefore its cultivation is confined to warm countries. Some authorities regard the mango as of medicinal value, and there is no doubt it serves as a mild laxative. On analysis of the mango juice we obtained the following results: Moisture, 81·35 per cent.; mineral matter, 0·57 per cent.; albuminous matters, 0·88 per cent.; malic acid, 0·20 per cent.; sugar, trace only; alcoholic extract (chiefly glycerine), 17·0 per cent. The mango possesses, it is interesting to note, anti-scorbutic properties which may be referred to the important quantity of alkaline salts present. The fruit may be consumed without harm by gouty and diabetic patients, since it is practically free from sugar, while the amount of free acid present may be disregarded.

HUXLEY'S PROTEID FOOD.

(THE ANGLO-AMERICAN PHARMACEUTICAL CO., GALEN WORKS, 59, DINGWALL-ROAD, CROYDON.)

We have received two forms of this food, one in which egg is used and one prepared without that addition. Our analyses practically confirm those already published. Food A (prepared without egg) gave the following results: Moisture, 15·70 per cent.; mineral matter, 8·30 per cent.; protein, 47·62 per cent.; fat, 1·0 per cent.; carbohydrate (chiefly cane sugar), 27·38 per cent. The preparation with egg (Food B) gave the following results: Moisture, 11·50 per cent.; mineral matter, 8·50 per cent.; protein, 48·86 per cent.; fat, 6·50 per cent.; carbohydrates (chiefly cane sugar), 24·64 per cent. There were present also sodium glycerophosphates and calcium formate. Finally, both foods are said to contain active lactic ferments, and in experiments upon milk we found this statement justified. Incubation over a period of 24 hours produced a steady increase of lactic acid and a curdling of the milk protein. It is claimed, further, that sodium glycerophosphate is present in a potential form—that is, it becomes available for the promotion of nutrition at the time of ingestion. The foods are of distinct merit and their composition has evidently been carefully worked

out, having regard to special physiological requirements. They are prepared chiefly for the use of sufferers from digestive disorders and those with feeble powers of assimilation.

BOULOU NATURAL MINERAL WATER.

(ST. LEGER, 24, ELSHAM-ROAD, KENSINGTON, W.)

The source of this interesting water is in the Pyrenees and its chief characteristic is the presence of an important amount of alkaline salts, sodium bicarbonate predominating. Further, it effervesces distinctly with carbonic acid gas, but does not contain an excess. The water is peculiarly soft to the palate and leaves an impression of cleanliness in the mouth. From its chemical composition it is clearly entitled to rank among those which are well known to be useful in catarrhs. It is particularly of service, for example, when taken freely and systematically in gastric catarrh and in certain intestinal disorders. It has a marked diuretic action. Our analysis showed that the water contained per litre 3·97 grammes of sodium carbonate, 0·91 gramme of sodium chloride, 0·97 gramme of calcium carbonate, 0·19 gramme of magnesium carbonate, and 0·10 gramme of silicic acid. There were present also salts of other metals, as, for example, manganese, iron, strontium, and potassium, but occurring only in minute quantities.

SOPHOL.

(THE BAYER CO., LIMITED, 19, ST. DUNSTAN'S-HILL, LONDON, E.C.)

Sophol is an interesting organic combination (formonuclein) of silver containing 20 per cent. of the metal. It is a dull-brown powder readily soluble in water. The compound is evidently a stable one, since the ordinary reagents of silver give no results when added to its solution. Sodium sulphide, however, readily separates the metal in the form of black sulphide. Sophol is introduced for use in ophthalmological practice, its merit, compared with other preparations, being that it is non-irritating, while it is an effectual destroyer of the gonococcus. According to experiments made with sophol, it appears to be a decided advance on silver preparations which have, so far, been employed in diseases of the eye.

VIBRONA.

(FLETCHER, FLETCHER, AND CO., HOLLOWAY, LONDON, N.)

The completion of new laboratories on modern hygienic principles for the purpose of preparing this wine on scientific lines is evidence of the manufacturers' determination to produce a standard article. When regard is had to the composition of a good genuine wine it is clear that on the face of it the constituents of cinchona bark must be practically incompatible with it. Perhaps tannin presents the greatest difficulty, since tannin precipitates most alkaloids. By the careful and ingenious processes adopted at the Vibrona laboratories a wine is produced which contains a definite and standard amount of cinchona bark principles in a thoroughly soluble and stable condition. The wine is quite bright and without deposit even after keeping for some time. One of the secrets of producing a permanently clear and bright product is the exposure of the preparation to a low temperature before bottling. Another important point is that the cinchona principles are present as hydrobromates, which are said not to produce the "cinchonism," which occurs in some patients when they take the ordinary cinchona preparations. We have examined a sample of Vibrona wine taken direct from the factory, and a sample purchased independently on the open market, and the results definitely support the claim that the wine is a carefully standardised preparation. In the one case, for example, we found a total alkaloidal content of 0·024 gramme per 100 cubic centimetres of the wine, while in the other the amount found was 0·026. This corresponds practically to the presence of cinchona bark constituents equal to five grains of the bark in two fluid ounces of the wine. While these results agree in regard to the active constituents present, there were unimportant variations in the amounts of alcohol, extractives, and mineral matters present in the two samples. Under medical direction the wine may serve an obviously useful purpose.

LIN AULAGNE.

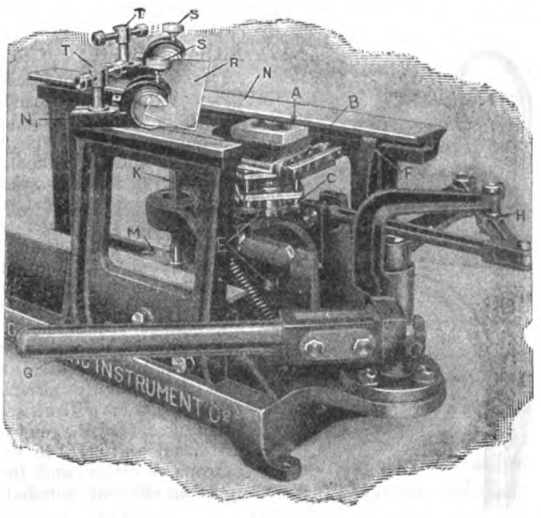
(E. AULAGNE, PARIS. AGENCY, ERNEST A. WHITE, 40, STANHOPE GARDENS, ILFORD, E.)

This linseed-meal poultice is most valuable and convenient in practice. It is very ingeniously constructed, and consists, it is stated, of specially prepared linseed (rendered antiseptic by boric acid), which is finely powdered over several layers of gauze, which are then compressed, sewn together, and made up in rolls from which a piece of any required size and shape can be easily cut off. On dipping the poultice in boiling water for a few minutes the meal absorbs a remarkable amount of water, the whole fabric becoming light and soft. An impermeable tissue is provided for covering the poultice during its application. We learn that the poultice answers admirably for suppurating wounds, whilst it can be readily employed as a mustard cataplasm by sprinkling a little dried mustard over the linseed. We regard the little appliance as an excellent help when a fomentation is needed.

New Inventions.

A LARGE SLIDING MICROTOME.

OUR attention has been drawn to a microtome that has been recently introduced by the Cambridge Scientific Instrument Company which presents some novel features that are worth notice. The instrument has been specially designed to cut sections of unusually large objects, the full size of a paraffin or celloidin block with which it is capable of dealing being 150 × 120 mm. (6 × 4¾ inches). It is built on extremely rigid lines; the two sides (N and N_1) support a large knife (R) which can be firmly held at each end in such



a way that it forms any required angle with the edge of the object to be cut; a new feature is an arrangement by means of which the surface of the knife can be tilted through a measured angle and adjusted to that which experiment has shown to be the one most suitable for the class of material it is desired to cut; for example, paraffin may require a different angle from celloidin, and decalcified bone from

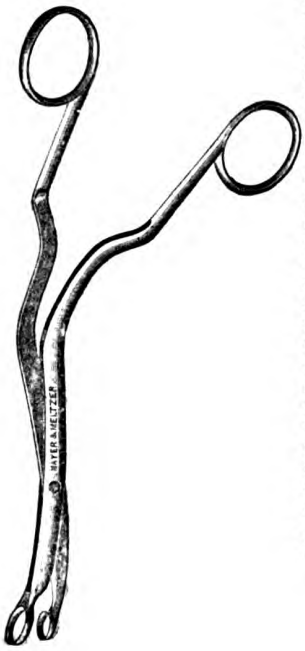
muscle or soft tissues. The block (A) containing the object to be cut is easily fixed to the object-holder, which can be adjusted to any position and is supported on a heavy carriage made to slide backwards and forwards by the movement of the lever (G). The guides of the carriage travel in two oiled chaunels, and it is claimed that all wear is automatically compensated for. The object-holder is fed upwards after each stroke of the lever by means of a ratchet and toothed wheel, while tearing of the material on its return journey past the blade of the knife is impossible owing to the fact that the surface remains low until its return is completed. The different parts of the machine are indicated by letters in the illustration but need not be pointed out in detail. The thickness of the sections can be varied from 0 to 0·06 mm. by adjusting an arm to a scale provided, each division on the scale corresponding to 0·002 mm. The object can be fed through a distance of 21 mm.

In practice the instrument has been found to work satisfactorily and to give no trouble; it is certainly necessary that great care should be exercised in embedding very large preparations, and attention should be given to such details as that of fixing the wood-block with absolute rigidity and of arranging the knife at the angle which is best for the particular material which is to be cut. No difficulty will be found in sharpening the knife on a good hone.

We have been especially impressed with the rigidity of the instrument and the thorough way in which the details of the construction have been carried out. The new features that have been embodied appear to fulfil most satisfactorily the purposes for which they have been designed. The possibility of being able to prepare microscopic sections measuring three or four inches in diameter, is one that will be readily appreciated both by those engaged in research, and perhaps even more by those whose business it is to teach normal and pathological anatomy, for, mounted as lantern slides, these sections project exceedingly well, and the advantage of being able to show what is practically a low power picture of a section on a screen in full view of any number of students will be easily understood. We understand that excellent contact photographic prints have also been obtained from sections cut by this instrument.

We have no hesitation in saying that its use will have wide applications in the future; its purchase should prove an economical investment, inasmuch as it is equally efficient for every class of work, and has all the appearances of being able to stand unlimited hard wear.

NASAL PUNCH FORCEPS.



I HAVE designed the forceps illustrated in the figure more especially for the removal of the anterior ends of the inferior and middle turbinated bones. They are made somewhat on the design of Luc's forceps, but the blades are made to punch or cut a piece cleanly out, and the peculiar jointing of the forceps ensures the accurate approximation of the cutting surfaces. I have used them in a number of cases and find them highly satisfactory, and they will also be found useful for the removal of septum and crest in submucous resection, and they form an efficient punch for removing portions of the tonsil. They are manufactured by Mayer and Meltzer, 71, Great Portland-street, London.

GEORGE W. BADGEROW, F.R.C.S.,
Senior Assistant Surgeon, The Throat Hospital, Golden-square, W.

CONVENTION OF THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

THE Twentieth Annual Convention of this association was held at Saratoga Springs, New York, on Sept. 13th, 14th, and 15th.

The President (Dr. Thomas D. Crothers, Hartford, Conn.) delivered an address on the Physics of Light Therapy.

The following reports of Standing Committees were presented: Dr. G. Betton Massey: On Direct Continuous Current, including Electrolysis, Electro-Chemical Surgery, Ionization, and all apparatus connected therewith. Dr. Frederick de Kraft: On Induced Currents, and apparatus. Dr. T. Harris Cannon: On Static Currents, and apparatus. Dr. S. M. McCollin: On Phototherapy, Radiotherapy, and apparatus. Dr. Fred H. Morse: On Mechanical Vibration Therapy, Exercise Therapy, and apparatus. Dr. Francis H. Munroe: On Hydrotherapy, Thermotherapy, and apparatus. Dr. Byron S. Price: On Dietetics. Dr. Thomas D. Crothers: On Research. Dr. W. Benham Snow: On Standard Therapeutic Measures.

The following papers were read:—Dr. Margaret A. Cleaves (New York): The American Electro-therapeutic Association; the Relation of its Work to Cellular Changes; a Retrospective *Résumé*. Dr. J. W. Torbett (Marlin, Texas): Report of X Ray Treatment of Spleno-Myelogenous and Lymphatic Leukæmia, with Blood Findings of Each. Dr. G. W. Strobell (Ruthland, Vt.): Report of a Case of Splenic Leukæmia Successfully Treated by Modern Methods. Dr. Louise G. Robinovitch (New York): Electric Anæsthesia in Human Surgery; Electric Sleep by Wireless and Unipolar Currents; Displacement Currents. Dr. Herbert McIntosh (Boston, Mass.): Psoriasis. Dr. J. D. Gibson (Denver, Col.): Some Blood Studies in Roentgen Therapy. Dr. William Benham Snow (New York): The Treatment of Inflammation. Dr. Frederick de Kraft (New York): Electricity in the Treatment of Gout. Dr. A. W. Baer (Chicago, Ill.): Treatment in Infantile Paralysis. Dr. Anthony Bassler (New York): Some Laboratory Findings in Diseases of Metabolism, which Question that these are Only of Metabolic Origin; the Rôle of Chronic Intestinal Disorders in the Production of Some of Them. Dr. Herbert F. Pitcher (New York): The Etiology and Treatment of Eczema. Dr. Frank E. Peckham (Providence, R.I.): Osteo-arthritis of the Spine. Dr. F. Howard Humphris (London, England): Lumbago. Dr. G. Betton Massey (Philadelphia, Pa.): The Treatment of Chronic Metritis with Decensus or Displacement. Dr. J. H. Kellogg (Battle Creek, Mich.): Light Baths. Dr. Samuel J. Harris (Boston, Mass.): Treatment of Cataract by Electricity. Dr. William J. Clark (Philadelphia, Pa.): Oscillatory Desiccation in the Treatment of Accessible Malignant Growths and Minor Surgical Conditions: a New Process. Dr. Fred. H. Morse (Boston, Mass.): Reaction Effects of Physical Treatments. Dr. Gustavus Werber (Washington, D.C.): Enforced Compensation. Dr. G. Betton Massey (Philadelphia, Pa.): Remarks on the Electrical Treatment of Interstitial and Hæmorrhagic Fibroids of the Uterus. Dr. J. Willard Travell (New York): A Noteworthy Case of Sciatica. Dr. W. Yale (Philadelphia, Pa.): Modern Malpractice in Gynæcology.

There was an interesting exhibition of electrical appliances for use in medicine and surgery, including two or three new electrodes for the purpose of administering fulguration, X ray tubes designed to withstand heavy currents, and a new form of static machine (a Baker modification of the Toepler-Holtz) which was capable of passing 7 or 8 milliampères through an X ray tube of medium hardness.

Dr. F. Howard Humphris (London) was elected a vice-president of the association.

ROYAL UNITED HOSPITAL, BATH.—Mrs. C. Baker of Bathampton has given £500 to the funds of the Royal United Hospital to endow a cot in the children's ward in memory of her late husband.

THE LANCET.

LONDON: SATURDAY, OCTOBER 15, 1910.

Medicine and the Church.[1]

SYMPOSIA upon disputed subjects are a literary device well known from classical times downwards by which conveniently to weld various opinions into a more or less harmonious whole; and the papers which are collectively issued under the title "Medicine and the Church" form an admirable epitome of the opinion held by leading clerics and physicians, together with some laymen, upon a matter which has of late years assumed a revived importance. Twelve writers have contributed towards the book in addition to the editor, who supplies an introduction, and the Bishop of WINCHESTER, who has contributed a "foreword." Among them are the Bishop of BLOEMFONTEIN, Sir CLIFFORD ALLBUTT, the Rev. Dr. ROBINSON, Prebendary FAUSSET, Dr. T. B. HYSLOP, Dr. JANE WALKER, Mr. STEPHEN PAGET, and the Hon. SYDNEY HOLLAND, all names which constitute a guarantee of sound thinking, and as a result we have a work of real and practical utility.

The question debated in the book is one which is as old as medicine itself, or, to be more exact, which supplied its own answer in the dawn of our profession. For at that day the priest and the medicine-man were one, as they are still among the few primitive peoples who are left on the globe, and whose ethics are known to us with any certainty. But as time went on, not only did the office and calling of the priest become divorced from that of the medical man, but, to speak generally, the first looked upon the discoveries of science with unbelief or positive antagonism, while the second in his turn took up an attitude of indifference or of enmity towards anything to which he could not apply the tests of reason. For many centuries, too, the science of medicine was upon a very low level, and no proper distinction was made between that class of disease which for want of a better name is called functional and that in which there is really some organic change. Hence arose cures—cures which appeared to be against the course of nature and were miscalled miraculous by those who forgot that great saying of ST. AUGUSTINE, quoted by Prebendary FAUSSET, "Portentum fit non contra naturam, sed contra quam est nota natura." After the Reformation the Church of England seemed, except in her formularies, to forget that her children had bodies as well as souls, while in the Roman Church the office of Unction of the Sick became transmuted into the unction of those who are leaving this life for the next. Nor was the profession of medicine blameless, for there was a tendency to treat the disease rather than the patient, and to consider as matters of no moment affections which, although they did not owe their origin to any gross disturbance of tissue, were nevertheless of very real moment to the patient. In cases of this sort the quack spiritual healer finds his widest opportunity, and owing to his vagaries the true usefulness of "mental healing" has been obscured. It is to throw light upon this obscurity, and to consider the field of function which belongs to both medical man and priest in their dealing with the sick, that the papers in the bock before us have been written. All of them are good and worthy of careful consideration both by medical men and the clergy. If we give special mention to those by Dr. H. W. G. MACKENZIE, Dr. T. B. HYSLOP, Dr. JANE WALKER, the second paper by Prebendary FAUSSET, and the contributions of the Bishop of BLOEMFONTEIN and Dr. ROBINSON, we none the less would not have missed willingly the two short contributions from Mr. STEPHEN PAGET and Mr. SYDNEY HOLLAND respectively, or the admirable little essay by Mr. ELLIS ROBERTS entitled "The Church and Mental Healing," which from the point of view of an educated man, who is presumably neither medical man nor cleric, sums up some difficult points in a very clear manner. Taken as a whole, the various papers set out an opinion much the same as that of the Lambeth Report of the Committee upon "Ministries of Healing"—namely, that there is room for both priest and physician in the sick room, and our own opinion tallies with this. There is no medical man who will deny the power of the mind over the body, no one who will not agree that if a patient desires to, and thinks that he will, get well, he is, *ceteris paribus*, in a much better position for recovery. Prayer, as both Dr. JANE WALKER and Dr. HYSLOP point out, whether as a personal habit or as offered for the sick by another, is of great value in securing mental stability and that quiet mind for which the Prayer Book contains a petition. A tactful and experienced priest may often be of the greatest assistance to a medical man, and no practitioner would, if his patient desired to see such an one, forbid his entry to the sick room. For the medical man knows that the ministrations of the wise priest constitute a very different affair from the folly or irreverence of "Christian Science."

The medical profession cannot be expected to take seriously the healings reported to the credit of Mr. JAMES M. HICKSON of the Society of Emmanuel; and to responsible clergymen who, seduced by the desire to preserve an open mind, may too easily credit such performances we would commend that warning of JEREMIAH, "I have not sent these prophets, yet they ran." The Office for the Visitation of the Sick, imperfect though it be and as the Lambeth Committee considered it to be, together with prayer by the sufferer himself, by his friends, and above all by the collective body of the Church in public worship, are far more efficacious than any ministrations by self-styled "spiritual healers." To quote the Bishop of LONDON, "If I was ill, I would send for the best doctor, and get my parish priest to come and pray by my side, believing that the double work of JESUS CHRIST is shared by two great professions. It would be bad for either to be banished from the sick room." The spirit of that sentence is, on the whole, the spirit of the collected papers contained in "Medicine and the Church," and, in our opinion, it is commendable.

Operations and Mortality.

FROM time to time the suggestion is put forward that sufficient care is not taken by surgeons in the selection of cases chosen for operation, and many of our lay critics go further and allege that in the performance of operations there is often an absence of a due sense of responsibility. To ensure that greater care shall be exercised in these matters it has been urged on more than one occasion that an inquiry—an inquest, in fact—should be held on all patients who die after an operation, a situation which was discussed in THE LANCET[1] last week from its medico-legal aspect. The latest enunciation of these ideas is contained in an article in the current number of the *Socialist Review*, where an attack is made on the motives prompting the performance of many operations, on the selection of the cases, and on the modes of operation often adopted. The article in the *Socialist Review* suggests that as an inquiry has to be held when a fatal accident occurs in a mine in order to find out if due precautions have been taken to prevent its occurrence, or if the incompetence or negligence of anyone connected with the mine is responsible for the result, so a similar inquiry should be held whenever an operation is followed by a fatal result. The first categorical accusation against operating surgeons made in support of this proposition is that surgeons do not use adequate thought in diagnosing the case before proceeding to operation, and that consultation with their colleagues is rare as a preliminary measure. In our experience the pains taken with regard to diagnosis are as a whole very great, while certainly an appeal to other members of the staff is the usual custom in most hospitals as well as in private practice. In cases of any doubt a consultation is practically always held, so that the main ground for this attack is cut away.

For these accusations form an attack, and the attack continues with the pronouncement that even if the diagnosis is correct an operation is often performed unnecessarily. If appendicitis, for instance, is present, need an operation always be performed? We are told that the operating surgeon says "Yes," while every medical practitioner knows that many cases of appendicitis recover without operation, that recurrence of the affection occurs only in a small minority of the cases, and that the mortality of the operation is appalling. We find it stated that while some surgeons give a mortality as low as 3 per cent., others give anything up to 20 or 25; but the writer of the article informs us "that every practitioner knows that some surgeons have a mortality of 100 per cent." Such statements exhibit the harm which results from a little knowledge, for we are more inclined to believe the writer ignorant of the subject than that he wilfully misstates the case. It is not possible with any utility to make any general statement as to the mortality of operations for appendicitis. During the interval between two attacks an operation will give a mortality of under 1 per cent. in the hands of all those who have had a real surgical training. On the other hand, when an appendicitic abscess has burst into the general peritoneal cavity, and has set up peritonitis unlimited by the formation of any adhesions, and especially when many hours have elapsed between the perforation and the operation, the death-rate must be indeed high. Without operation death is certain; with an operation suitable for that state and condition of the patient some cases will recover. We do not believe that the practice of any surgeon will show a mortality of 100 per cent. in operations for appendicitis, as the writer asserts. Further, he maintains that a high mortality indicates a lack of judgment in diagnosis or incompetence in the execution of the operation, and he makes this statement without the least regard to the stage or severity of the disease. Somewhat similar statements are made with regard to operations for brain tumours, from which, we are told, not one in a hundred recovers. The purpose of the paper is stated to be the expression of the belief of the need for measures to be taken by the State to ensure that only justifiable and legitimate operations should be performed. The remedy suggested is that the State shall compel all hospitals, public, private, and cottage, to be registered, and to publish a percentage of recoveries for each disease and operation. The names of the physicians are to be given; in the case of a surgical operation followed by death the operating surgeon, whether in hospital or private practice, is to notify the coroner and an inquiry will forthwith be held. We have quoted sufficient from this paper to show the animus of the writer, who prefers to remain anonymous, sheltering himself behind letters representing academic distinctions. We do not admit the accuracy of the statements made by him. His statistics are worthless and the conclusions based on them are naturally untrustworthy, while his ignorance of the factors upon which mortality depends betrays him into crude fallacy.

None but the ignorant would venture to deny the value of modern surgery. As Professor WILLIAM THORBURN in his introductory address at the University of Manchester pointed out last week in our columns, the progress of surgery has resulted in an immense saving of life, limb, and suffering. Within the last 25 years at the Manchester Infirmary the death-rate from all causes after operation has fallen from 10·5 to 8·5 per cent., in spite of the fact that now nearly three-fourths of the patients in the surgical ward are operated on as against one-fourth 25 years ago. While in 1883 20 per cent. of the deaths after operation were due to infective conditions, now only 1 per cent. is due to such causes. There is a natural conservatism in many members of the medical profession, and the resistance to progress which manifests itself in opposing many suggested alterations in practice is by no means small. We would not for a moment imply that every modification of surgical treatment is necessarily an advance, indeed we wrote to the contrary effect quite recently. Yet there will always be found too many ready to cry out that a new procedure is unnecessary or even harmful. When anæsthesia was first introduced there were not a few who urged that anæsthesia was unnecessary for operations, as will be seen by reference to the medical periodicals of the time. It is true that patients have died from anæsthetics since; it is true that patients in the future will die from anæsthetics, however carefully, however judiciously administered; but

[1] THE LANCET, Oct. 8th, 1910, p. 1099.

shall we therefore refuse to avail ourselves of these valuable agents in operation? Let us think of the thousands, of the tens of thousands, who have benefited by this great step in advance in surgery. We regret the deaths; we would modify our procedure in any way which would avoid such a distressing occurrence as death from anæsthesia; and it may be that in the future some safer methods of anæsthesia may be produced. But meanwhile we cannot, we must not, refuse to avail ourselves of the use of anæsthetics during operations. There are ever those who are ready to cry unjustifiable when some new operation is proposed or performed. When ovariotomy was first introduced the unfavourable results led many members of the medical profession to consider that the operation was unjustifiable, and that any operator performing it deserved prosecution for manslaughter. But, in spite of this intense opposition, a few surgeons persisted. In Sir SPENCER WELLS'S first hundred cases there was a death-rate of 34 per cent. With each hundred the mortality diminished, and in his tenth hundred the death-rate was only 11. We may be sure that if any mechanism had existed in those early days of ovariotomy for bringing Sir SPENCER WELLS'S results before a coroner's inquest, in many of the cases a verdict would have been returned that he had performed an unjustifiable operation, and the result of such a verdict would have been the misery and death of thousands upon thousands of women. Ovariotomy has become a comparatively safe operation and the mortality of to-day is much less than it was 30 years ago. In the words of Sir JOHN ERICHSEN, "The procedure, formerly so fatal as to be pronounced unjustifiable, is now the most successful of all great surgical operations."

Much progress has been made, and many operations which were inconceivable a few decades ago are now widely and successfully performed. Nothing would tend to stem the onward progress of surgery so much as to make a surgeon liable to have his work tried before a coroner's jury, for that is what it amounts to. Inquiry would be made as to whether the operation were justifiable; as to whether it were performed with skill and care; and evidence would be taken on these points. The only persons present at the majority of operations, in addition to the surgeons, are the house surgeon, the dressers, and the nurses. Shall these be called upon to accuse or to justify the actions of the surgeon? We can imagine a certain sort of nurse, not necessarily the best sort, giving evidence as to the suitability or the capability of the surgeon, and we have little doubt that the jury would be more inclined to accept her evidence and opinion than those of the surgeon himself. Even a surgeon of equal competence to the operator himself, and present at an operation, is not always capable of judging of the difficulties encountered so well as the surgeon who does the operation. Then we cannot imagine a tribunal less fitted for deciding questions as to the desirability of an operation or the capability of a surgeon than a coroner's jury. The possibility of having to appear for trial before such a body would doubtless deter many surgeons from performing operations where the risk to life was great. And yet every experienced surgeon can tell of numerous lives saved by a timely operation in which the prospect of success was not great. If the patient and his friends know the risk of the operation and the chance of life if no operation be performed, and if they agree to the performance of the operation and the surgeon is willing to do it, who shall say them or him nay? The very life blood of true progress in surgery is the devising and the carrying-out of new operations or the employing methods unknown before; but what would be the result if the performance of a new operation or the use of a hitherto unknown method might subject the surgeon to the ordeal of a public trial? Few men would take the risk of unmerited public obloquy; and many, many patients would perish miserably.

A Historical Martyr.

CIRCUMSTANCES have made the death of MIGUEL BOMBARDA, our respected colleague, into a historical event of the first importance. One of ARISTOTLE'S many political inductions, repeated by subsequent thinkers, as, for instance, by HERODIAN in his sequel to SUETONIUS, that revolutions are often brought about by causes apparently accidental, nay, relatively trivial, has its latest illustration in the sudden change of government in Portugal. True, as ARISTOTLE himself and the chroniclers of Rome's decline and fall knew all too well, the causes in question would have had no effect but for predisposing circumstances which only awaited opportunity to find their inevitable issue. Still, the interesting fact remains that the assassination of a medical man, beloved as a citizen and in great request as a consulting alienist, was the occasion that gave direction and power to a vigorous and perhaps far-reaching explosion, not unexpected, but certainly startling, by which the world awoke at the end of last week to find the Portuguese monarch a fugitive and a Republican government established over the capital city of Lisbon. Dr. BOMBARDA was, by the most authentic account, professionally engaged in his consulting-room when a former patient, a lieutenant in a regiment of the line, who had with a certain measure of success been treated for cerebral derangement, called to report himself. In the course of the interview, in a sudden access of his ailment, he discharged three shots from a loaded revolver at the unfortunate BOMBARDA. One of these had taken deadly effect in the abdomen, but the victim, summoning up his fast-ebbing strength, overpowered his assailant just as his servants rushed into the room in time to hear his dying words: "Don't harm him. He is mad."

The incident is one of the most pathetic in the annals of the medical profession, as surely its sequel was one of the most dramatic. No sooner was the assassination known than the popular indignation, all too apt to "see its own in another's wrong," became possessed with the conviction that the crime was brought about by official instigation, or, at least with official cognisance, opponent as BOMBARDA was of the party in power, nay, representative in the recently elected Parliament of the Republican interest. Not even the authentic words that absolved the wretched assailant from premeditated crime could avail for a moment to stem the rising tide of resentment and revolt. The deed was loudly proclaimed as quite in keeping with the policy and procedure of the Royalist party, and the Liberals were

prompt to describe the incident as but the latest in a series of oppressive and despotic acts. Such was the instantaneous impression and comment of the piazza, and in this way the psychological moment arrived for the revolutionary explosion, the subversion of the old order, and the planting of the new *régime* on its ruins. It is not for us to forecast the political consequences of this movement, or its effects, immediate or remote, on the country itself or on Europe in general. We have but to record our sense of loss at the untimely, the tragic, end of an able and accomplished representative of the healing art in a sister country, whose skill as an alienist and energy as an organiser were appreciated far beyond the city in which he taught and practised, and whose last words, we hope, will prove a bequest to his compatriots to temper justice with mercy, and to use their newly acquired power in the humanitarian spirit in which he lived and died.

Annotations.

"Ne quid nimis."

PHARMACEUTICAL EDUCATION.

IT is highly probable that before many years have gone by the system of pharmaceutical training and education at present in vogue will undergo a fundamental change. The Council of the Pharmaceutical Society recently obtained powers to require candidates for the statutory examination to undergo a defined course of study, and the question of devising an appropriate course is now under consideration. In the meantime there is no compulsory curriculum of study for pharmaceutical candidates, and it is no part of the duty of the Council or the Board of Examiners to inquire of candidates how or where they obtained their knowledge. Some years must necessarily elapse before the projected changes can be put into force, and the pamphlet entitled "How to Become a Pharmacist," edited by Mr. John Humphrey and published by the Pharmaceutical Press (price 1*s.*), provides those who desire to adopt pharmacy as a career with all the information about the necessary qualifications. The first step to be taken is to pass one of the preliminary examinations approved by the Pharmaceutical Society, such, for example, as the matriculation examination or the senior school examination of the University of London. Then follows an apprenticeship of three years, during which period the student should have ample opportunity to make practical acquaintance with the methods of manufacturing galenical preparations and to obtain experience in dispensing physicians' prescriptions; if he is fortunate, the student will also be able, during his apprenticeship, to attend classes at one of the numerous technical schools and so obtain elementary instruction in some of the subjects of the minor examination. When the apprenticeship is completed it is usual, and for the vast majority of students essential, to attend a course of lectures and laboratory instruction at a school of pharmacy. The Pharmaceutical Council recommends that such a course of instruction should occupy a period of not less than six months, and that such period of study should include 60 lectures in chemistry, 45 lectures and demonstrations in botany, and 25 lectures and demonstrations in materia medica. Judging from the high percentage of unsuccessful candidates at the qualifying examination, it seems evident that the council's advice is often neglected. The subjects of the examination are botany, chemistry and physics, practical chemistry, materia medica, pharmacy, practical pharmacy, and dispensing and prescription reading. The examination is of a searching character, and all who pass it should be capable of carrying on the business of pharmacy efficiently. The pamphlet also contains particulars of the "major" examination, which confers the title of "pharmaceutical chemist" on successful candidates. In addition, it includes information concerning various scholarships and prizes.

FALLS FROM GREAT HEIGHTS.

FALLS from great heights, not necessarily fatal in their results, are becoming so frequent in these days of aeroplaning that it may prove of interest to refer back to the classics of the subject, which, however, are not as ample as might be expected. Writing in 1841 of a fall from an immense altitude which did not result in death, a French observer, M. Manzini, declares that he had searched in vain in the annals of science for a similar case. We can well believe it. The victim or patient was a *tapissier*, who had been engaged in putting up decorations, on the occasion of the belated obsequies of Napoleon the Great, in the lofty dome of the Church of the Invalides in Paris. When busy moving a ladder on the top of a high scaffolding he overbalanced himself, and, in obedience to some obscure instinct, jumped clear of the ladder and the platform, crying to his fellow workmen, as only a Frenchman would, "Tiens, me voilà parti!" With these cheerful words on his lips, he fell 82 feet, bounding in one place off the roof of a little dome, which caused him to describe a second parabola in the air, and landing finally, feet first, on the slate roof of a small sacristy. Crashing through the slates, he landed astride a rafter, where he was found sitting, surprised but coherent, for he was able to give his name and address when asked for them. He had no recollection of this, and became unconscious when put to bed shortly afterwards under the care of the great Pasquier. His insensibility lasted a very short time, however, and he made an extraordinarily rapid recovery, having sustained no apparent injuries either external or internal. At the end of a month Pasquier found him quite well. Manzini also records the case of his own fall from a great height when a child, and describes the feeling of blindness that came upon him, due to the rapidity of his descent, also the anguish of recovering his breath after it. Others, however, describe their sensations during a tremendous fall as being far from disagreeable. Thus, some nine years ago Professor Heirn, the geologist of Zürich, described "the flood of thought" that traversed his mind during a typical Alpine fall, which began on an inclined plane. He saw beautiful scenes and visions of his past life as he fell, and reflected rationally on his death or the chance of escape. He felt no pain on striking the ground, but he heard a thud, which was the impact of his own head on a rock. Another Alpine faller thought about his insurance and his family. "Of the losing of my breath, of which people talk, there was no suggestion, and only the heavy fall on the snow-covered ground caused me to lose suddenly and painlessly all consciousness." Both these Alpinists insisted on the absence of anxiety from their minds when falling, while one certainly describes sensations similar to those felt by the drowning. Among classic English falls may be mentioned that of a steeple-jack, who in 1800 fell from the top of the church of St. George in Bolton-le-Moors to the ground, the whole distance traversed being some 120 feet. The man's skull struck some sheet lead upon the earth and left its impact upon it, but though this fall was quite unbroken as in the previous cases by scaffolding, rocks, and so forth, the man was only slightly injured and resumed work in a few days.

Recently a man with his boots on fell from the top of a cliff at Dover, the height of which was afterwards found to be 400 feet. He was picked up floating insensible in some five feet of water, but his boots were off, which proves that he must have retained sufficient consciousness on reaching the water to enable him to draw his boots from his feet. Both these cases are well attested. We wish we could be as sure of the truth of the story told of an *ouvrier*, who fell from a fourth-floor window and who, as he passed a lower one, was heard to remark with great rapidity and clearness, "Ca va bien jusqu'à présent pourvu que ça dure!"

THE ACTION OF ATOXYL ON THE EYE.

THE discovery of the action of atoxyl and other complex organic arsenical compounds upon trypanosomes and spirochætes has caused them to be widely studied and extensively employed in numerous diseases. Unfortunately, atoxyl, in spite of its name and of its undeniable usefulness, has not proved to be entirely harmless, since a considerable number of cases of blindness following upon its use are now on record. These recorded cases are critically studied in an interesting article published in the *Berliner Klinische Wochenschrift* of Oct. 3rd by Dr. Kurt Steindorff of Berlin. He has been able to collect records of as many as 95 cases of disturbance of vision or actual blindness following on the use of atoxyl. It would seem that the onset of the ocular symptoms is often preceded by some evidence of toxic effects—such as general languor, vertigo, headache, vomiting, colicky pains, dysuria or anuria, hypothermia, tinnitus, and deafness. The ocular symptoms comprise a more or less marked diminution of the power of sight, and the field of vision is concentrically diminished, but more on the nasal than on the temporal side. The ophthalmoscopic examination at first gives negative results, save that the retinal arteries may be narrowed, the veins somewhat hyperæmic. After a few weeks the papillæ begin to appear pale, and the condition progresses with uncomfortable rapidity to complete optic atrophy, associated with increasing dimness of vision going on to complete blindness. The prognosis of the ocular symptoms is the more grave from the facts that the immediate stopping of the drug does not, as a rule, suffice to stop the progress of the condition, and that treatment has so far proved unsuccessful. In the majority of cases the blindness must be attributed to the atoxyl and not to the diseases for which it is given, since in most of these optic atrophy is a rare occurrence. It would appear that alcoholism predisposes to the development of atoxyl amblyopia, and that an eye already the subject of latent damage from other poisons, such as arsenic or mercury, is also more likely to be affected. Some cases published by Watermann showing a rapid diminution of vision in cases of tabetic optic atrophy lend some support to this view. A study of the doses and of the intervals of administration of the drug in the recorded cases throw but little light upon the subject. Beck suggests, however, that the most dangerous conditions are those in which small doses are given daily for long periods without intervals, and those where large doses are injected with very short intervals. The method of administration, whether intramuscular, subcutaneous, or subarachnoid, does not appear to exert any special influence upon the incidence of atoxyl amblyopia, nor do questions of sex, age, or severity of the disease for which the drug is given. The pathology of the condition is obscure, but it appears to be a simple progressive atrophy. So far Dr. Steindorff can only find one case recorded—that of Nonne—which has been examined microscopically. Unfortunately, the retina was not examined, but the optic nerve showed symmetrical degeneration by Marchi's method. This extended back to the chiasma. There were no inflammatory manifestations. The question as to whether the arsenic or the anilin constituent of the atoxyl molecule is responsible has been much discussed; both substances do in rare instances lead to ocular disturbance, but this is usually of the nature of an optic neuritis rather than a primary atrophy, as is the case with atoxyl. The general conclusions arrived at by Dr. Steindorff are that the atoxyl exerts its toxic effect directly, or that it is converted in the eye into some more poisonous reduction product. The substance arsacetin, introduced by Ehrlich, although less toxic than atoxyl, is less active therapeutically, and ocular disturbances have even been observed after its use. Dr. Steindorff, while admitting the value of atoxyl and allied substances, counsels the utmost care in their use. His interesting review of the subject has a useful bibliography of the recorded cases attached to it, and affords a valuable study of this important subject.

THE ROYAL VISIT TO SOUTH AFRICA.

ON Oct. 11th the Duke and Duchess of Connaught left London *viâ* Southampton for South Africa, where His Royal Highness will open the first Union Parliament on Nov. 4th. The programme of the Royal tour, which has just been issued, is a long one. The *Balmoral Castle*, in which the Royal party will travel, will on the outward voyage call at St. Helena, where the various visits will include one to the hospital. The programme for South Africa includes the presentation of St. John Ambulance certificates by His Royal Highness and the laying of the foundation-stone of University Hall at Cape Town, a visit to the hospital at Livingstone, a visit to the hospital and schools at Buluwayo, and the laying of the foundation-stone of the new university building at Pietermaritzburg. On Dec. 3rd the Royal party will leave Durban for England.

ANCIENT ANATOMICAL DRAWINGS FROM TIBET.

THE military expedition which reached Lhasa in 1904 has made us acquainted with some remarkable anatomical drawings of a very early date. A set of these drawings, which were found in the "Temple of Medicine" at Lhasa, was deposited in the India Office Library by Lieutenant-Colonel L. A. Waddell, C.B., I.M.S., together with some thousand volumes of rare and also of unknown treatises, including several on medicine. Lieutenant-Colonel Waddell has given a description of the drawings in the *Asiatic Quarterly Review* for October, 1910, and a faithful copy, made by a native artist, was presented some time ago by Major H. J. Walton, I.M.S., to the Museum of the Royal College of Surgeons of England, where it is now shown in the historical cabinet. The anatomical drawings show many points of affinity with those of early Greece. Some centuries before Alexander's invasion of India (325-27 B.C.) Rawalpindi in Northern India was famous as a place of medical learning, so that there may have been an exchange then between the medical centres of the east and west. In Lieutenant-Colonel Waddell's opinion the anatomical charts now found in Tibet were obtained from Northern India in an early Christian century. The main chart shows three figures, the central being described as a "chart for identification of the internal parts of the body." The right-hand figure, a female, is inscribed, "The method of disposition of the five deep veins for ascertaining the cause (of disease), and the superficial middle vein of the mystical circle of the breast." The left-hand figure, a male, bears the legend, "Delineation of the inner vessels (showing) the mode of connexion of the eight great veins of the hidden systems." The position of the blood and bile vessels in the right and left halves of the male body were supposed to be reversed in the female. The drawings cannot be said to show an accurate knowledge of anatomy. The blood and bile vessels are the parts which receive most attention. The Indian Buddhist origin of the chart is shown

by a row of 12 monks bearing Indian names, represented at the top of the drawing. We congratulate Lieutenant-Colonel Waddell on the interesting contribution which he has made to our knowledge of medicine in ancient India.

INTERMISSION OF PERNICIOUS ANÆMIA FOR 17 YEARS.

IN the *American Journal of Medical Sciences* for August Professor Alexander McPhedran of Toronto has recorded a case of pernicious anæmia in which there was complete intermission of the symptoms for the remarkably long period of 17 years. The patient was a physician, aged 49 years, engaged in a large country practice. He had been losing strength and growing anæmic for a year or two. He became so ill that he had to cease work in the spring of 1889. There were recurrent chills, a temperature of 104° F., marked delirium, severe vomiting, and diarrhœa. The skin was very pale with a lemon tint. The blood showed the characteristic changes of pernicious anæmia, the red corpuscles numbering 730,000 per cubic millimetre. There were retinal hæmorrhages in both eyes. Arsenic was given in increasing doses until 45 minims of Fowler's solution were taken daily. Improvement took place, and in a month the red corpuscles numbered 1,700,000, and in another month 3,250,000. Five months later the number of red corpuscles was normal and he appeared to have completely recovered and was able to resume practice. He remained well until the autumn of 1906, when he found himself growing weak and unequal to his work. When examined in March, 1907, he was very weak and of yellowish colour. He suffered from constipation with occasional diarrhœa. The red corpuscles numbered 1,926,000, and were generally large; poikilocytosis was marked, and both normoblasts and megaloblasts were present. The hæmoglobin was 39 per cent. He improved rapidly, and by the end of the month the red corpuscles numbered over 3,000,000 and there were no megaloblasts. In the early summer the corpuscles numbered over 4,000,000 and he felt correspondingly improved. He went to the Canadian North-West as far as the Rocky Mountains. Vomiting and diarrhœa were troublesome and he was much prostrated. Under rest he improved and was fairly well on his return in November. He was not seen again until January, 1908. He looked well, although his strength was failing. The appetite was fair, the tongue was clean, there was no stomatitis, the gums were healthy, the teeth having been removed some years previously. There was some diarrhœa for a day or two every fortnight; the stools were liquid but not offensive. The red corpuscles numbered 3,500,000 and showed only slight variation in size and shape. From this time he became gradually worse, with slight improvement for a few days from time to time. Vomiting frequently occurred. He became semi-conscious and died at the end of a month on May 17th, 1908, at the age of 68 years, over 20 years after the first symptoms appeared. He recovered from these, and remained in good health for 17 years, but during this period there was no opportunity for blood or other examination as he felt quite well and considered such unnecessary. A necropsy was not granted. The duration of the disease and the length of the intermission appear to be the longest recorded in the literature of pernicious anæmia. Indeed, the latter was so long that Professor McPhedran regarded the case as an example of permanent recovery, and had the patient died from pneumonia or other cause the case could with good reason have been so recorded. He suggests that in all the cases of permanent recovery claimed a relapse would have occurred if the patient were not cut off by some intercurrent disease, and he therefore differs from the statement made by Professor W. Osler: "When a patient has been six years free from trouble it seems safe to conclude that no recurrence will occur." The present case is a striking illustration of the uncertainty of the course and duration of pernicious anæmia. In many cases the prostration has been so great that death has been daily expected, and yet recovery has quickly taken place to the extent that the patients could resume work. As to the value of arsenic, Professor McPhedran finds that it is in the more acute cases, if in any, that it is beneficial. In these there are the symptoms of an acute toxæmia—fever, vomiting, diarrhœa, and often delirium. The arsenic is well borne, and as soon as the vomiting and diarrhœa cease improvement is often rapid. In the more chronic cases with progressive symptoms, often without acute irritative attacks but running slowly a downward course, he finds that arsenic is seldom beneficial, and causes stomatitis and gastro-intestinal disturbance. This is illustrated by the present case; in the first acute attack arsenic was well borne and recovery was rapid, not necessarily because of the arsenic; in the second attack even small doses caused stomatitis and epigastric distress.

REST-CURES FOR THE POOR.

A CORRESPONDENT has recently drawn attention in the press to the defect which exists in this country in the provision of accommodation for those of the sick poor whose affections require treatment by rest. That neurasthenia and analogous disorders exist among the class from which hospital out-patients are drawn there can be no sort of doubt, for the out-patient departments of the general hospitals furnish numerous examples, while the similar departments of the special hospitals dealing with nervous disorder overflow with such cases. Without committing ourselves to an opinion that the "work-shy" are invariably of a neurasthenic diathesis, we are sure we are not over-stating the case when we affirm that many such are incapable of work because they present just those symptoms which are characteristic of some of the functional disorders. The effect of being out of work is well known among those who labour for the benefit of the unemployed. No matter how willing a man may be to work, he is, after the privations and anxieties of a period of unemployment, incapable of the quantity or quality of effort which he was wont to exhibit in former times, and it is found to be idle to expect it of him. But it is scarcely for such cases as these that provision for treatment is demanded. There is a very large number of individuals whose daily work is beyond their physical capacity and who, further than this, are harassed by temporary or, worse still, long-continuing worry. Such factors as these are alone sufficient to produce nervous exhaustion, and if they are assisted in their nocuous action by the weakly character of the nervous system of the particular person who is subjected to them, disaster is very likely to ensue. Some small provision is, in fact, made for the treatment of patients of this class. Very occasionally they may be found in the wards of a general hospital, and rather more frequently in the wards of the three hospitals devoted to the treatment of nervous disorder which exist in London. There can be but little doubt that if these particular hospitals, instead of being almost constantly pressed for money, met with more general support far more could be done in the provision of rest-cures for the poor than is now possible. We have from time to time expressed a hope that the day may not be far distant when advantage may be taken of the generous gift made, now some years ago, by Dr. Henry Maudsley for the purpose of building a hospital for mental disorder. Our own aspirations are for an institution which may combine out-patient departments, wards for the treatment of organic nervous disorder, functional nervous disorder, and mental

disorder—if the two latter can in fact be separated legitimately one from the other—a department designed for the reception of those for whose lesions there is no hope of repair, and lastly, teaching and pathological departments. In such an institution there might be hopes of ample accommodation for those requiring rest-cures. Institutions of like character are possible in lesser and poorer cities in other countries, and we see no reason why Dr. Maudsley's gift should not be utilised as a basis upon which to rear in the largest city in the world such a structure as we have outlined.

A SCHOOL STRIKE.

COMPLAINTS are not seldom heard of the difficulty of impressing parents of the working-classes with the necessity for sanitary precautions in the matter of infectious disease. At Booker, near High Wycombe, however, the lesson appears to have been learnt almost too well, for the zeal of the fathers and mothers to protect their children who should be attending the council school has recently reduced the attendance there from 100 to 20 scholars, owing to the fear that they may become infected by contact with the children of the caretaker at the local isolation hospital. It is stated that the parents refuse to be convinced by the school medical officer, and that they not only decline to send their children to the school, but have combined in censuring the sanitary authority for employing as caretaker a man with a young family. The strike, if such it may be called, must have met with willing support on the part of the children, who are probably not otherwise composed of strict sanitarians, and who possibly do not pay as willing attention to measures useful for preserving their health, such as brushing their teeth and observing personal cleanliness, as they do to their parents' desire that they should enjoy a holiday.

THE ACTION OF HUMAN FŒTAL EXTRACTS UPON MALIGNANT TUMOURS IN MAN.

Dr. Fichera, continuing his research work on the biology of implantations of fœtal and neoplastic tissues, contributes to the *Policlinico* an important paper on the Action of the Products of the Autolysis of Human Fœtal Tissues upon Malignant Tumours in Man. Previous experiment on rats had shown the resistance which could be induced in otherwise susceptible rats to implantation of malignant tumours by previous implantation of fœtal tissues, and, further, that injection of the products of autolysis of such tissues could inhibit the growth of implantations of malignant tumours, implantations which in the ordinary course of events would have invariably caused death. The observations upon the human subject were begun in September, 1909. Thirty-six cases have been treated, all past surgical cure; 29 had been previously operated on. In all cases the diagnosis was established histologically, and in all cases during the progress of the case microscopic examinations were made of fragments removed by excision, in some cases as often as eight times. Of the 36 cases, 14 abandoned the treatment almost at the commencement for various reasons; 4 cases, though favourable, were of too recent date to pronounce upon, so that 18 cases remain. Of these, 8 have shown no improvement. Of the other 10, 5 are reported cured and 5 are well on the way to complete cure. The 5 complete cures are composed of 3 cases of carcinoma of the breast with multiple metastases, 1 case of carcinoma of the terminal portion of the rectum, and 1 adeno-carcinoma of the thyroid gland. The injection may be given either at the site of the disease or at a distance. Injections at the site of the disease give rise to areas of hæmorrhage and necrosis, while injections given elsewhere in the body cause mainly cytolysis with a moderate growth of connective tissue to replace the tumour. Metastases are often extremely sensitive to the autolytic action and may disappear without leaving any trace. Large tumours, on the other hand, require a long course of treatment before the malignant growth is wholly replaced by connective tissue, and especially where local injections have been practised there may remain a large tumour of sclerotic connective tissue in place of the original growth. The constitutional effects of the injection are very different, according as to whether they are made into the tumour or at a distance; in the former case there may be a sharp rigor with temperature 102° to 104° F., while the same dose given in some other part of the body will give rise to no disturbance. This initial disturbance Dr. Fichera considers a toxic phenomenon, and explains its production in the case of local injections by the abundance and fragility of the vessels in the tumour, and by the possible entrance into the circulation of the products of the cytolysis of the new growth. The action of the fœtal extract he considers direct and selective, and gives a number of good reasons for this view. From this follows a relation between the dose injected and the size of the tumour. To avoid the use of too big a dose he has recourse to the more energetic action of the injection at the site of the disease; also in the case of large tumours he would advise excision of the tumour in addition to treatment by injection. The extracts used were made from fœtuses of from two to six months of intra-uterine life. The tissues are placed in physiological saline solution with the addition of a certain quantity of thymol or carbolic acid, and sterile olive oil or toluol is placed on the top. The mixture is kept in the thermostat at 37° for about two months. The dose is 2 or 3 cubic centimetres, and this is injected from two to four times a week. The treatment lasts a variable number of months.

ISABEL THORNE.

MEDICAL women have lost a valued friend and supporter by the death of Mrs. Isabel Thorne, who for more than 30 years was honorary secretary to the London School of Medicine for Women. Her early married life was spent in the East, and she soon became aware of the need for medical women in India and China. On her return to England about 1868 she endeavoured herself to obtain a medical qualification, but at that time no medical school would admit women, nor were qualifying examinations open to them in Great Britain. Miss Elizabeth Garrett had obtained the L.S.A. diploma, but this privilege had been denied to other women. In 1869 the Senate of the University of Edinburgh decided to admit women to the study of medicine in separate classes, and Mrs. Thorne, with others, went to Edinburgh. The following unanswerable and eloquent appeal made by Sophia Jex-Blake, a medical student at Edinburgh, and published in THE LANCET of July 9th, 1870, will serve to show the position taken up by women students and the nature of the opposition they had to overcome. "State clearly what attainments you consider necessary for a medical practitioner; fix your standard where you please, but define it plainly; put no obstacles in our way; either afford us access to the ordinary means of medical education, or do not exact that we shall use your special methods; in either case subject us ultimately to exactly the ordinary examinations and tests, and if we fail to acquit ourselves as well as your average students reject us; if, on the contrary, in spite of all difficulties, we reach your standard, and fulfil your requirements, the question of 'mental equality' is practically settled so far as it concerns our case; give us, then, the ordinary medical licence or diploma and leave the question of our ultimate success or failure in practice to be decided by ourselves and the

public." Unfortunately for the adventurous band of lady medical students in Edinburgh the General Council of the University, by a majority of one, rejected the proposal to admit women to the same classes and privileges with men as students of medicine. The next step was to star a school of medicine for women in London, and Mrs. Thorne became its honorary secretary, living to see her life's work crowned with success and rewarded by the knowledge that it had achieved a safe place and recognition among metropolitan medical schools.

AN UNUSUAL CASE OF URÆMIA.

CASES of uræmia present numerous phenomena and combinations of symptoms. The diagnosis is frequently difficult, especially when the nervous system is involved. In another column we publish an interesting case recorded by Dr. G. Parker, in which facial paralysis and intestinal ulceration were almost the first symptoms noted. In the paralytic form of uræmia hemiplegia may occur suddenly without any gross lesion being discovered after death; a monoplegia may also show itself, but peripheral facial paralysis is rare, and, as Dr. Parker remarks, it is difficult to determine its exact pathology. Various attempts have been made to explain the nervous disturbances in uræmia. One theory is that the resulting symptoms are due to the action in the nerve cells of the poisons generated by the disease circulating in the blood-stream. Another theory is that the symptoms are produced by the cerebral œdema or cerebral anæmia causing excitation or paralysis of the nerve structures. Possibly in the case we are considering, Dr. Parker's suggestion that the facial paralysis was due to a hæmorrhage or œdema in the structure of the nerve is the correct one. The severe hæmorrhage from which the patient suffered was probably due to secondary inflammation of the bowel which may occur in chronic renal disease and which may occasionally assume an ulcerative form. The resistance of the tissues to the invasion of microbes is considerably diminished in disease of the kidneys, and hence not only are the mucous membranes likely to be attacked, but the malady frequently assumes a serious form and death often occurs. Dr. Parker gives a good account of his case and his remarks on the pathology of the symptoms noticed are interesting and instructive.

THE EHRLICH-HATA PREPARATION IN THE TREATMENT OF MALARIA.

IT was inevitable that a method of treatment which claims the power of killing pathogenic parasites within the body without damaging the tissues should be applied to the cure of other diseases than syphilis only. H. Werner has used "606" in the treatment of malaria at the Hamburg Institute for Marine and Tropical Diseases in 22 cases, and gives a brief report of his results in the *Deutsche Medizinische Wochenschrift* of Sept. 29th. Eleven of his cases were of the tertian and 11 of the æstivo autumnal type. A most interesting feature of the results was the difference between the reaction of the two types. In the tertian cases injection was followed, in an average period of 24 hours, by disappearance of parasites from the peripheral blood; moreover, so far as observations covering some weeks show, they did not reappear except in three cases in which the dosage had been below the average of 0·6 gramme. In the æstivo-autumnal cases the results were by no means so encouraging. In five instances a single dose sufficed to banish the parasites from the peripheral blood, but this was only temporary, and within a few days they reappeared. In the remaining six cases of the æstivo-autumnal type the treatment had no effect upon the circulating parasites. Various methods were used; at first intra-muscular injection was practised, then the subcutaneous and intravenous methods, and in the last case a combination of the two latter. Apparently no untoward consequences were noted. Werner's opinion is that "606" is a powerful antimalarial remedy, but its use should be restricted to cases resistant to or intolerant of quinine.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND: MUSEUM DEMONSTRATIONS.

THE courses of demonstrations, instituted some years ago by the Council of the Royal College of Surgeons of England in connexion with the Museum, are likely to become permanent additions to the advanced teaching resources of medicine in London. An autumn course is to be given by Dr. A. Keith and Mr. S. G. Shattock, Hunterian Professors of the College. The first demonstration will be given by Dr. Keith in the theatre of the College, Lincoln's Inn Fields, on Friday, Oct. 21st, at 5 P.M., when specimens will be shown which illustrate obstruction of the bowel produced by (1) defects of the diaphragm; (2) by peritoneal pockets; and (3) by imperfect fixation of the mesentery. On Monday, Oct. 24th, at 8 P.M., Mr. Shattock will deal with the specimens which illustrate lesions of syphilis. On subsequent Fridays and Mondays, as will be duly noted in our "Diary of the Week," the following sections of the Museum will be dealt with: specimens illustrating the various forms of imperfect differentiation of sex in man, specimens illustrating the lesions of rickets and cretinism, specimens of acromegaly and of the injuries and diseases of arteries. The demonstrations are open to all medical men and advanced medical students.

WE have learned to our great regret of the death of Professor Ernst von Leyden, the successor of Traube at the Berlin Clinic. His address at the Twelfth International Medical Congress at Moscow in 1897 on "Contemporary Methods in the Treatment of Tuberculosis," in which he advocated the notification of phthisis and maintained that all the various points in a successful scheme of treatment were only obtainable in a properly conducted sanatorium, drew much attention at the time and formed the subject of a leading article in our columns.

THE opening address of the winter session at the Central London Throat and Ear Hospital will be given at 4.30 P.M. on Monday, Oct. 17th, by Dr. Purves Stewart on Certain Intracranial Diseases associated with Nasal, Aural, and Laryngeal Symptoms, illustrated by lantern slides. The annual dinner of the medical staff of the hospital will take place the same evening at the Trocadéro Restaurant, when Mr. W. Stuart-Low will occupy the chair. Past and present students desiring to attend are invited to apply to the secretary.

THE Gresham Lectures, consisting of four lectures on Ancient and Modern Surgery, will be delivered by Dr. F. M Sandwith, Gresham Professor of Physic, on Oct. 25th, 26th, 27th, and 28th, at the City of London School, Victoria Embankment, E.C. The lectures are free to the public and will begin each evening at 6 o'clock.

WE regret to announce the death of Dr. John Anderson, C.I.E., the well-known authority on tropical diseases, which took place on Monday last, Oct. 10th. He had been a complete invalid for many months.

MEDICAL GOLF AT BATH.—A match was played at Bath last week between teams representing the medical men of Bath and Bristol respectively, and resulted in a very easy win for the latter team.

RADIUM AND RADIO-ACTIVITY.

ABSTRACT OF AN ADDRESS BY DR. GUYENOT.

AN interesting lecture directing attention to the therapeutic application of radio-active substances was recently delivered to the Medical Society of Aix-les-Bains by Dr. Guyenot, director of the Physio-Therapeutic Institute of that place. The lecturer, after giving an attractive sketch of the history of the discovery of radium and of the investigations which led to the revelation of its remarkable properties, proceeded to describe its physiological action, the first evidence of which, he said, was on the skin, as M. Becquerel found to his cost on several occasions. The tips of his fingers, which had come into contact with tubes and capsules containing radio-active substances, became hard, white, and very tender. The inflammation lasted about a fortnight and was followed by shedding of the skin. The tenderness, however, persisted for upwards of two months. Becquerel, too, was the victim of another accident which has become famous. In April, 1901, he took up a tube containing very radio-active chloride of barium and put it in his waistcoat pocket. His assistant warned him that it was somewhat risky, but he paid no attention and went off with the tube. It was a sealed tube wrapped in paper and enclosed in a cardboard box. The rays, though weakened by the several layers, were powerful enough to excite phosphorescence through his clothes. M. Becquerel kept the tube in his pocket six hours, and a few days later, without having felt any pain, he noticed a patch of redness on the skin, which gradually grew darker, its outline corresponding to the shape of the tube. The skin was shed on April 24th, leaving a suppurating wound which took 45 days to heal. During this time a second oblong patch made its appearance, corresponding to another corner of the pocket that had held the barium. It having been less exposed to the action, the inflammation did not supervene until 35 days after the contact and was only superficial. This action of radium on the skin has led surgeons to try its effect in the external treatment of certain skin diseases and tumours of various kinds. These burns are similar to those produced by the X rays, with the same period of incubation, running the same course, and ending in the same way.

In regard to the action of radium on bacteria, X rays are not bactericidal, whereas radium is markedly so, especially certain of its rays (the alpha rays). Ashkinas and Strebel found that cultures of B. prodigiosus were attenuated by radium rays. Caspari tried the effects of radio-active injections on tubercle bacilli introduced into the anterior chamber of the eye of a guinea-pig and on the diphtheria organism introduced into the muscles and no infection followed. Pfeiffer and Friedberger placed 25 milligrammes of bromide of radium, with a radio-activity of 50,000, 6 centimetres from a culture of the typhoid bacillus for 24 hours without any result, but at a distance of 1 centimetre the growth was completely arrested. Similar experiments carried out by Hoffmann arrested the development of the staphylococcus and the bacillus anthrax. As regards the action of radium on ferments and toxins, the rays act in different ways on the various ferments. Some lose their efficacy, while others are not affected or are rendered more active. Invertin and emulsin (Victor Henri and André Mayer), hæmolysin (Danysz) and lactic fermentation (Ch. Richet) are attenuated, while, on the contrary, proteolytic ferments, pepsine and pancreatin (Bergell and Braunstein) are rendered more active. According to Tizzoni and Bongiovanni, the rays exert a very marked influence on the virus of hydrophobia. Not only do infected spinal cords that have been exposed to the rays no longer transmit the disease, but they can be utilised for vaccinating purposes. Phisalix tested the influence of radium emanation on the toxicity of venoms and found that while serpent venom lost its toxicity, those of the salamander and toad were not affected thereby.

As to the action of radium on the nervous system, this is seen in the fact that when small animals are exposed thereto we get certain nervous symptoms. When X rays are brought to bear on small animals we often get symptoms of paraplegia, but only when intense radio-dermatitis has been produced, so that we are not in a position to distinguish between a direct and a transmitted nervous lesion. No such difficulty presents itself with regard to radium, the central nervous system being vastly more sensitive to its influence than is the skin. For instance, by the introduction beneath the skin of a mouse a month old of a tube containing about 1 centigramme of radium with a radio-activity of 500,000, placed exactly over the spinal column and part of the skull, within three hours we get symptoms of paralysis. In seven or eight hours the mouse is seized with convulsions, and if the tube be left *in situ* these become more and more frequent and the animal dies in from 12 to 18 hours. Mice a year old do not die for from six to ten days. The lesions appear to vary according to the age of the animals, and according as the nervous system is or is not protected by bony or cartilaginous tissue. Death is rapid in young animals, whereas in adults it is slow, or we may only get atrophic lesions (London). The larvæ of insects placed in glass boxes along with a tube of radium are paralysed in 24 hours and die in two or three days, and here, again, it is the nervous system that seems to suffer most (Danysz). M. Danysz also investigated the action of radium on small animals at a distance, and he found that the effects were much the same but took longer to be produced. Experiments have been carried out to ascertain the action of radium on the peripheral nerves. Beck applied a tube of radium over the trunk of the sciatic nerve of 13 rabbits and five dogs. In eight complete anæsthesia and analgesia were produced. Rehns found that sensation returned in the anæsthetic patches of tabetic patients when radium was applied. Zimmern and Professor Raymond succeeded in attenuating lightning pains and the hyperæsthesia in neuralgia and neuritis. This latter fact had been previously noted by Darier, who relieved the pain in several cases of facial neuralgia by the application of radium. Radium has an action on the retina, on the reproductive glands, on the lymphoid organs, and on the blood.

The physiological action of the emanation and induced radio-activity is well known. Radium produces the emanation persistently without any appreciable loss of weight, so that we have here a practical means of utilising radio-activity in the form of the emanation. Curie and Danysz investigated this action on particular organisms. Caterpillars placed in a tube of the emanation were paralysed much in the same way as by the radium rays. Bouchard, Curie, and Balthazard made similar experiments with guinea-pigs and mice, and the animals died after a stage of loss of heat and torpor. The rapidity with which the fatal result is produced depends on the quantity of emanation contained in the atmosphere in which the animals are placed. London obtained similar results with frogs and mice. The emanation is perhaps more rapidly microbicidal than the direct rays. Danysz killed with it a culture of anthrax bacillus. Dorn, Raumann, and Valentiner found that the emanation in a gaseous form arrested the growth of the typhoid bacillus on gelose and killed it outright in solid media and in culture bouillon through which the gas was allowed to bubble. Mouse typhus, the comma bacillus, and the diphtheria bacillus are similarly affected. The physiological action of the emanation introduced into the organism has been studied more especially in Germany. Madame Anna Laska carried out a series of experiments at the Charity Hospital at Berlin and reports the following results: Rabbits were given by the mouth or by intravenous injection radio-active water—i.e., water that had been rendered radio-active by the radium emanation. The amount of emanation introduced into the blood current was soon eliminated *viâ* the lungs. This result is in accordance with theory, which would lead us to expect the emanation to escape through the lungs. It also proves that the emanation taken by the mouth remains in the organism longer than when injected into the veins, no doubt owing to the fact that in the digestive tract the emanation is only gradually absorbed. Examination of the blood in the course of these experiments yielded the following results. In one case in which the animal had been given 120 centimetres of radio-active water a tangible proportion was found in the blood. In all the other cases the quantity of emanation was so small that it could not be measured. This is explained by the fact that the emanation no sooner gets into the blood than it is got rid of in the breath. Several investigators have discovered traces of the emanation in the urine. Examination of the fæces revealed the fact that a tangible amount of the emanation taken by the mouth is eliminated *viâ* the intestine. The stomach, liver, and cartilages contain insignificant quantities of emanation.

Another author, Dr. Silbergleit, carried out a series of experiments at the Medico-Policlinic at Berlin in order to ascertain the influence of the emanation on organic exchanges. Radiogenic water was administered to three young men free from any rheumatic or gouty taint. No. 1 took his radiogenic water after lunch, composed of bread and meat, followed by complete rest. No effect on the gaseous exchanges was noted. In the two others the radiogenic water was given on an empty stomach in the morning, still with the subject at rest. In both there was a notable increase of the gaseous exchanges.

Uric acid, as we know, circulates in the blood in the form of urate of soda, of which there are two isomeric forms, differing from each other by their respective solubility in the blood plasma. The soluble salt is converted into the insoluble form. In gout and similar states this transformation is so rapid that the normal excretion of the uratic salt is unable to take place. Dr. Gudzent investigated the effects of the emanation and found that the conversion of the soluble into the insoluble salt was notably checked and did not set in again until the emanation had been eliminated. A course of treatment with radiogenic water would consequently seem capable of preventing the deposit of urates in the tissues and so conceivably obviate the recurrence of attacks of gout.

Dr. Nagelschmidt and Dr. Kohlrausch have published the results of their researches bearing on the physiological influence of radium-therapy, and arrived at the following conclusions. The emanation of radium may be regarded as a gas capable of absorption by the lungs, the stomach, and the intestine. The greater part of the emanation is eliminated *viâ* the breath in a comparatively short time, a small part escaping in the fæces, and a still smaller part being stored up in the liver and bile. As long as the emanation remains in the organism it gives off rays that permeate the tissues and produce exactly the same effects as radium rays. Curie and Laborde ascertained the proportion of radium emanation contained in the gases and waters of a number of thermal springs, and various authors have investigated the biological action of mineral waters laden with emanation, and recognise that they exert a stimulating influence on the ferments of the economy. As Laborde remarks, we cannot but be struck by a coincidence that almost amounts to a revelation when we find that the mineral waters so far found to be most radioactive are those with low mineral contents. This seems to justify the assumption that the well-marked effects obtained at various mineral water stations are possibly due to the radio-activity of the waters, since they cannot be due to the small proportion of mineral constituents. This seems the more probable, judging from Löwenthal's experiments, who gave healthy men a certain quantity of water laden with emanation without the production of any tangible effect, whereas in persons suffering from chronic articular rheumatism it determined a febrile attack with pain and swelling of the joints.

There are several ways of employing radium in therapeutics. It is in surgery that it was first turned to account. The extremely violent action of radium on the tissues renders special precautions necessary. First we must apportion the quantity of rays to be brought to bear in each case, then we must protect the healthy tissues against the unnecessary and injurious action thereof. Lastly, the method of application varies according to the individual requirements. It must be borne in mind that the rays emanating from radium are not simple, they comprise several kinds of rays which differ from each other by their mode of action and by the degree of penetration into the living tissues. This has led specialists to devise special instruments and appliances, as complicated as they are ingenious. Radium seems to exert a specific action on cancerous and angiomatous tumours. It has yielded remarkable results in certain forms of cancer, in keloids and vicious scars, in angiomata and pigmented nævi, in cutaneo-mucous tuberculosis, and in certain varieties of chronic, pruriginous, inflammatory dermatosis.

According to Dominici and Gy, radium gives good results in gonorrhœal arthritis, obstinate neuralgia, and neuritis. As to the internal and external use of the emanation, however, we are no longer on sure scientific grounds. In passing, it may be mentioned that radium emanation is contained in a certain number of natural mineral waters, and this cannot surprise us because a sheet of underground water may conceivably come into contact with radiferous earths and so acquire the properties of induced radio-activity. It is, indeed, interesting to note that certain mineral waters which are recognised to be very efficacious are precisely those containing comparatively large quantities of emanation. The radio-activity of mineral waters only exists at the source, for the water soon loses its borrowed properties. Possibly this may explain why there is such a difference between the therapeutical effects of mineral waters "consumed on the premises" and those drunk at home.

Numerous physicians began to try whether water that has been rendered artificially radio-active is capable of exerting a beneficial action in affections in which the naturally radioactive mineral waters display most efficacity, among them being Dautwitz, Lowenthal, Laqueur, Kraus, Jacobs, Bergel, and Bickel. Dr. Lowenthal remarks, and the observation is worthy of note, that waters rendered artificially radio-active provoke a reaction characterised by an increase of the pain and the reappearance of inflammatory symptoms in the originally damaged joints. This reaction corresponds exactly to a phenomenon with which we are familiar in the thermal treatment of rheumatic and gouty affections. Radium cannot very well be utilised as such for internal administration, in consequence of its intense action on living tissues, and this has led physicians to make use of the emanation in internal radium-therapy as well as for certain external applications. The problem has been solved by the construction of emanation apparatus. In these the radium is surrounded by water, to which it communicates uniform qualities of emanation. The quantity of emanation in this water can be measured in units by the electroscope. The emanation apparatus consequently produces a solution of the emanation in stated doses, and such water can be used for baths or taken internally, or it can be utilised to increase the radio-activity of a mineral water, to be employed as directed.

The external application of the emanation may take the form of baths, compresses, or mud poultices. With regard to baths, it is probable that the effects are due to inhalation of the emanation in the water vapour and not to transcutaneous absorption. The prescribed quantity of radioactive water is added to a bath at the ordinary temperature in which the patient is left for about half-an-hour, stirring the water frequently. Compresses are prepared of various sizes. Before being applied they are steeped in boiling water, wrung out and placed round the joint or over the nerve trunk, waterproof being placed outside. To be left *in situ* 12 hours. The compress can only be used once and the process of reinforcing it takes some four days. Radioactive mud is a very convenient mode of application. It is prepared by mixing powdered pitchblende with twice its volume of hot water. This is applied direct to the part to be treated; it is easy to use and can be left on several hours under a piece of waterproof. This mud exerts a sedative effect and is believed to promote the absorption of exudations. It does not excite any irritation of the skin or give rise to inconvenient reaction, its radio-activity is permanent, but when it has been used it must be allowed to dry for a fortnight before using again.

The emanation can be given in two ways—viz., as a drink and by inhalation. The prescribed number of units is obtained by adding a suitable quantity of radiogenous water to a mineral water, which must be drunk forthwith, taking care not to shake it up too much. Patients who are taking large doses must be closely watched and in presence of symptoms of violent reaction the treatment must be modified or suspended. For inhalations a special apparatus is employed, the radiogenous water being heated and the vapour inhaled by the patient. Each sitting lasts three or four minutes.

What, then, are the principal indications for the therapeutical application of radium? On comparing the results obtained in Germany and in France one cannot but be struck by the singular unanimity of views of the observers, all the more so, seeing that this concordance is rather rare in medicine. It is to be noted that the Germans do not quote French investigators, nor the French German authorities; moreover, the researches were carried out at about the same period. The German school lay down the following indications: (1) muscular rheumatism, chronic and subacute articular rheumatism, and all forms of chronic arthritis; (2)

gonorrhœal arthritis and rheumatism; (3) neuralgia, especially sciatica, neuritis, and the lightning pains of locomotor ataxy; (4) catarrhal affections of the respiratory tract, pharynx, and larynx; and (5) affections of the frontal and maxillary sinuses. The French indications have been summed up by Dr. Claude, of the St. Louis Hospital, as follows: (1) rheumatoid arthritis; (2) gonorrhœal rheumatism; (3) various arthropathies; (4) diseases of the nervous system; and (5) certain cutaneous and gynæcological affections. The only difference to be noticed between the French and German authors is in the mode of application. In France the treatment consists mainly of baths and mud poultices, whereas in Germany considerable importance is attached to the ingestion of water laden with emanation.

THE FIFTH INTERNATIONAL CONGRESS OF OBSTETRICS AND GYNÆCOLOGY,[1]

HELD IN ST. PETERSBURG UNDER THE AUGUST PATRONAGE OF HIS IMPERIAL MAJESTY THE CZAR OF ALL THE RUSSIAS.

THE following delegates from Great Britain and Ireland were present at the Congress: Dr. Amand J. Routh (London), representing the Royal College of Physicians of London, the Royal College of Surgeons of England, Charing Cross Hospital Medical School, and the Obstetrical and Gynæcological Section of the Royal Society of Medicine; Dr. Thomas Wilson (Birmingham) and Dr. Jervois Aarons (London), representing the Royal Society of Medicine; Dr. Edward Malins, representing the University of Birmingham; Sir Alexander R. Simpson, representing the Edinburgh Obstetrical Society; and Mr. M. G. McElligott, representing the Royal College of Surgeons in Ireland.

On Sept. 21st in the large Alexander Hall of the Hotel de Ville a reception was held by the municipality. The Mayor, I. I. GLAZOONOFF, who received the guests together with the members of the municipality, welcomed the members of the Congress as individuals who, he said, were fighting for the health of their wives, mothers, sisters and daughters, and who were therefore appreciated by all, because the health of a woman is a care for which every gynæcologist strives.

On Sept. 22nd the Congress was opened with the Russian National Hymn. The president of the committee of organisation, Professor Dm. O. OTT, expressed his satisfaction that the Congress which had been twice delayed could now at last take place, and spoke of the institute, which is a building of the highest technical perfection and which is destined to be the perfection of obstetrics and gynæcology in Russia. Next the honorary curator and administrator of the Imperial Clinical Institute of Gynæcology and Obstetrics, General-Lieutenant ANTCHOOTIN, declared the Congress open, whereupon the Mayor again welcomed the members of the Congress.

The chief secretary of the Congress, Professor P. SADOVSKY, read his report. He mentioned the difficulties in arranging the Congress in the year 1905 because of the revolution in Russia, and in this year because of the cholera. But now, thanks to his Majesty the Emperor and to all the Members of the Government, as well as to the committee of the Congress, it was possible to have a reunion of many eminent members of the gynæcological and obstetrical profession. Professor Sadovsky mentioned with regret the names of several gynæcologists who had died since the last Congress—Kufferath, Pfannenstiel, Budin, Edebohls, Engelman, Etheridge, Porro, Reverdia, Skene, Acconci, Rösthöm, Barnes, and Macan. He proposed in the name of the committee to form a Society of the International Congress of Gynæcology and Obstetrics to assure a regular convocation of congresses, and to prevent such delays as had happened with this Congress.

In order to allow the members of the Congress to make better and more intimate acquaintance with each other one of the *salons* of the Hôtel d'Europe was reserved for their exclusive use.

[1] We are indebted to Dr. Jervois Aarons for furnishing us, through Dr. H. Macnaughton Jones (Honorary President for Great Britain), with a précis of the proceedings of this Congress, from which the following notes are abstracted.

THURSDAY, SEPT. 22ND.

FIRST SESSION.

Presidents of honour: Professor BEUTTNER (Geneva), Dr. BUMM (Berlin), and Dr. DÖDERLEIN (Munich).

Professor LUIGI MANGIAGALLI (Milan) read a paper on

The Therapeutics of Inoperable Cancer of the Uterus.

He said: In cases when surgical intervention is not possible or not to be recommended we possess many means which seem to impede if not to stop completely the progress of a neoplasm, and which give us hope for the future—namely, pharmacotherapy (mercury, arsenic, condurango, chelidonium majus, quinine, charcoal, cholesterin), jequirity, opotherapy (orchidean and thyreoidean), fermentotherapy (trypsin, amylopsin, cholesterin), bacteriotherapy (Coley's fluid, vaccinotherapy, serum of Doyen, streptococcic toxins of Emmerich and Scholl, blastomycetic serum of Wlaeff and Sanfelice, cancroin of Adamkiewicz, nectrianin and antimeristem of Schmidt), röntgenotherapy, radiumtherapy, and fulguration.

Professor A. STICKER and Dr. E. FALKE (Berlin) communicated a paper on

The Treatment of Inoperable Cancer by Ferments combined with Radium.

Inoperable cancer, they said, can be ameliorated and sometimes cured by the use of ferments, whose action is increased by a combination with radium. This new method combines the disintegrating and reabsorbing properties of the digestive ferments (e.g., trypsin) with the action of radium. These actions are not only added to but rather multiplied. The best vehicle is charcoal, because it has the greatest absorptive power for the ferments as well as for the emanation of radium. The preparation used by the authors is a combination of charcoal with trypsin—carbenzym plus barium carbonate of radium. In this practical form the dissolution of the albumins under the action of the ferments is continued and prolonged, while the radioactive substances give the highest tension and duration of emanation.

Dr. R. LOURIE (St. Petersburg) read a paper on the Action of Radium, of X Rays, and of Fulguration on the Tumours of Mice, which was followed by a paper on Experimental Investigations into the Origin of Metastases in Cancer by Professor E. OPITZ (Düsseldorf), and another on Early Intervention in the Treatment of Cancer of the Uterus by Mrs. CL. OOLEZKO-STROGANOVA (St. Petersburg).

Professor OPITZ, in the discussion which followed the reading of these papers, said that he had seen a little amelioration after fulguration according to Keating-Hart, but then new proliferations began. The use of acetone was painful. He recommended the administration internally of potassium iodide and the local use of calomel as a dusting powder after the wound had been curetted. Then locally there could be observed a reaction combination of iodine and mercury.

Dr. SELLHEIM (Tübingen) showed a series of preparations exhibiting the great danger of ordinary curettage and cauterisation of cancerous wounds.

Dr. BARREIRO (Mexico) showed the utility of diathermia, which was applicable where the lancet was not, and spared the tissues which must be saved. The bones were no obstacle to its use; no part was too hidden, and no passage too narrow where an electrode could not be placed. There was no hæmorrhage, the tissues were sterile, no dissemination of germs or cancerous cells, orientation and the localisation were easy, and recurrences were exceptional if the whole tumour had been influenced.

Dr. RIVIÈRE (Paris) stated that 15 years ago he used the treatment by sparks before it was spoken of as electrocoagulation or fulguration; this fact was proclaimed by him in 1900 at the Congress of Electrical and Physical Therapy held in Paris.

Dr. KADER (Cracow), Dr. STRASSMANN (Berlin), and Professor STICKER also took part in the discussions.

The paper of Dr. MACNAUGHTON JONES (London) was not read owing to the absence of the author.

FRIDAY, SEPT. 23RD.

SECOND SESSION.

Presidents of honour: Dr. KADER, Dr. MALINS, and Professor MANGIAGALLI (Milan).

Dr. LE FILLIATRE (Paris) demonstrated a Casque Bavette for Laparotomy and a Dilator for the Suprapubic Operation.

Professor BEUTTNER read a paper and demonstrated a new method of Bilateral Ablation of the Adnexa of the Uterus.

Dr. BUMM read a paper on

The Leading Principles of Cæsarean Section.

He discussed the advantages and disadvantages of the supra-symphysic section over the classical operation on the fundus of the uterus, and expressed the opinion that in aseptic cases the choice of method is not important, and for feverish women with a septic genital canal neither method is secure, for the danger depends on the kind of infection, decomposition of the liquor amnii by ascending putrefactive germs being less dangerous than the presence of streptococci.

Dr. PESTALOZZA (Rome) read a paper on

The Cæsarean Operation.

He was of the opinion that extra- and intra-peritoneal methods of Cæsarean section have each precise indications, the classical operation being always preferable where asepsis is certain. When this is uncertain the extraperitoneal operation should be performed, but in cases of certain infection embryotomy was indicated and no Cæsarean section was safe.

Dr. AMAND ROUTH read a paper on

Cæsarean Section in Great Britain and Ireland.

He showed from statistics of all operations performed in the United Kingdom since 1867 how the lessened risk of Cæsarean section had widened its range of usefulness, and considered it in the circumstances of obstruction to labour, uterine hæmorrhage, and constitutional crises.

Dr. E. P. DAVIS (Philadelphia) read a paper on

Cæsarean Section for Conditions other than Contracted Pelvis.

Six cases were discussed—2 of central placenta prævia, 1 of inactivity of the uterus, 1 of multiple fibromata, and 2 of toxæmia on the basis of insufficiency of the thyroid gland.

Dr. DÖDERLEIN (Munich) followed with a paper on Hebosteotomy with Extraperitoneal Cæsarean Section.

THIRD SESSION.

Presidents of honour: Dr. MARTIN (Berlin), Dr. ROUTH, Dr. ROSNER (Cracow), and Dr. PESTALOZZA (Rome).

Professor OPITZ read a paper on

The Value and Choice of the Different Methods of Cæsarean Section.

He said: In aseptic cases the classical Cæsarean section and the suprapubic are equally advantageous, but the secondary infection of the uterine wound cannot be excluded. If infection is possible, a wound in the depth of the pelvis is less dangerous than a wound situated higher in the abdominal cavity. The danger can be diminished by draining through the posterior vaginal cul-de-sac. The opening of the abdominal cavity and the flowing out of the amniotic liquid are of no great importance. Therefore, in making the suprapubic Cæsarean section it is permissible to open the abdominal cavity and then to go between the bladder and the uterus to make its neck more accessible to the incision. By sewing the wound with the bladder and the peritoneum it is placed extraperitoneally. The method of Latzko is the best for the operation if completely extraperitoneal, but it makes a very large wound in the cellular tissue which may be dangerous. Therefore the method of Latzko-Doederlein is to be adopted only in exceptional cases.

Dr. PANKOW (Freiburg) read a paper on Hebosteotomy *v.* Cæsarean Section.

Dr. SELLHEIM read a paper on

The Modern Methods for the Improvement of the Technic of Cæsarean Section,

of which the following is a summary. For Cæsarean section, as long as no great haste is demanded, the Pfannenstiel transverse incision is preferable to the median incision, for it allows a better shutting off of the free peritoneal cavity during and after the operation, and further pregnancies can progress without disturbance. In evidently infectious cases with a marked abnormal relationship between child and parturient canal, all operative deliveries, with exception of the reduction in the size of the child, are dangerous. But the risk may be minimised through an improved management of labour. From 46 cases of Cæsarean section performed by different methods Professor Sellheim had lost five mothers and six children. In two patients the extraperitoneal Cæsarean section was repeated and no complications were observed. In general the success of the extraperitoneal Cæsarean section is so great as to raise the question in what degree this operation could take the place of the classical Cæsarean section, of hebosteotomy, and of vaginal Cæsarean section.

Dr. KHOLMOGOROFF (Moscow) read a paper on the

Different Methods of Cæsarean Section (Classical, Vaginal, and Extraperitoneal).

The classical method required special precautions and experience; the extraperitoneal method was good for cases where infection was suspected. The vaginal Cæsarean section ought not to be opposed to these operations, but only to operations performed in cases where no delay was possible. This method had all the advantages of the others, which were long, difficult, and more dangerous.

Dr. COVA (Rome) read a paper on Extraperitoneal Cæsarean Section according to the Method of Latzko, which was followed by a paper by Dr. VAN DE VELDE (Haarlem) on

Hebosteotomy v. Cæsarean Section.

For cases of moderate contraction he preferred to use hebosteotomy, in other conditions Cæsarean section. In cases of infection the first operation was less dangerous. After hebosteotomy he had observed 13 following labours, and in seven cases had found that the pelvis remained dilated.

Dr. FRANTZ (Cologne) read a paper on Subcutaneous Hebosteotomy and Suprasymphysic Delivery.

Dr. MORAVSKY (Cracow) read a paper on an

Addition to the Question of the Extraperitoneal Section.

He described nine cases of Cæsarean extraperitoneal section operated on during one year. The great advantage of this operation was that the abdominal cavity remained intact. This method could be used in cases where the classical Cæsarean section could not be undertaken.

SATURDAY, SEPT. 24TH.

The hour from 9 to 10 A.M. on this day was given up to demonstrations.

Dr. CRÉDÉ-HOERDER (Munich): Anatomy of the External Genital Organs of the New-born. He had found the following differences between the adult and the new-born. In the latter the ligamentum suspensorium clitoridis was very large. The configuration of the corpora cavernosa clitoridis and urethræ was quite different. The corpora were larger than in adults. The funiculi spermatici were enormously large. The ligamenta teretia of new-born boys were very feeble. The septum scroti was enormously developed. The testes were very small. The epididymis and the corpuscles of Morgagni were very large. The bulbus urethræ in the new-born was formed as in an animal. The corpora cavernosa urethræ in the new-born girl were convergent, which was not the case in an adult. The microscopic examination showed that the præputium was very developed and it took up two-thirds of the whole length of the penis.

Dr. MARTIN showed 35 pictures illustrating the topographical anatomy of the genital region of the woman and insisted on the importance of knowing this region, especially in cases of prolapsus of the bladder and of the uterus.

FOURTH SESSION.

Presidents of honour: Sir A. R. SIMPSON and Dr. SOOBBOTITCH (Belgrade).

The question which came up for the consideration of the Congress at the session was the Vaginal Route in Obstetrics and Gynæcology.

Dr. MARTIN read a paper on

The Vaginal Route in Gynæcology.

The vaginal peritoneal operation, colpotomy, had been essentially improved by the paravaginal incision and Ott's lighting instruments. It had thereby been freed to a considerable extent from the objection of an insufficient way to the operative field and of want of comfortable eye control. Colpotomy was indicated by special groups of displacement and deformity of the uterus, inflammation of tubes and ovaries and peritoneum, by the earliest stages of ectopic gestation and special forms of neoplasmata of the uterus and ovary. It was less serious than laparotomy and gave favourable immediate and remote results. It was not alternative to laparotomy, but answered special indications. Vaginal operations were indicated for those cases where

plastic surgery was necessary for correction of the position of the uterus and the vagina, modification of the hypertrophy of the uterus which was formerly called chronic uteritis, chronic inflammations of the peritoneum of the pelvis and the organs contained therein, and not very hard nor very large peri-uterine adhesions; in early cases of extra-uterine gestation with a sac which had not burst; and after rupture when the shock was over. Tuberculous states were better attacked from above. In cases of collapse the diagnosis could be only presumptive, therefore it was better to operate by abdominal section. Myomata of the uterus and tumours of the ovaries should be operated upon not according to their size but according to their mobility and their connexion with other organs. Neoplasms, the malignity of which was suspected, must be operated on abdominally.

Professor JUNG (Göttingen) read a paper on

Theses of the Report about Bossi's Method, Metreurysis, and Colpohysterotomy.

The rapid and forced dilation of the cervix uteri with Bossi's instrument during pregnancy or parturition should be rejected when the cervical canal was not dilated and regular and strong labours had not preceded. Primiparæ ought not to be delivered at all with Bossi's dilator. Also placenta prævia was a strict contra-indication against its use. When multiparæ were in question and the cervical portion was already dilated and drawn upwards, Bossi's instrument, handled by a skilful and well experienced obstetrician, might give good results in single cases. The practitioner, however, ought to be strongly advised against the use of the instrument on account of the ever-threatening danger of deep lacerations of the cervix. In all cases in which the confinement was to be accelerated but not to be brought to an end immediately, also in cases of placenta prævia when the fœtus was alive, metreurysis was the best and safest proceeding. The treatment of placenta prævia by colpohysterotomy was only permissible in the clinic, and even there only in the case of placenta prævia totalis. Also for induction of labour the introduction of a metreurynter into the uterine cavity was the most advisable procedure. In those cases in which the pelvis was normal and the woman had to be delivered immediately, colpohysterotomy should be chosen for treatment in the clinic. The practitioner who was single-handed should in such cases apply metreurysis. Contraction of the pelvis reaching the second and third degree and the child being alive required the abdominal Cæsarean section, supposing the patient was not infected. Should infection exist, then the head of even the living fœtus must be perforated; eventually Porro's operation must be performed.

Dr. FRAENKEL (Breslau) read a paper on

The Vaginal Incision.

He proposed to drain the vagina with his instruments and according to his technique, not only in cases of opening abscesses, but also to assist the resorption of inflammatory products in the cellular tissues of the large ligaments. According to his opinion, operative intervention was but rarely indicated for peri uterine inflammations; the vaginal incision was the first and the most efficacious agent in resorptive therapy.

Dr. DUETZMANN (Berlin) read a paper on Vaginal Methods of Operation, which was followed by a paper by Dr. STRASSMANN on the Perfection of the Vaginal Methods of Operation with the Use of the Anterior Flap Incision.

Dr. KOROBKOFF (St. Petersburg) read a paper on

Ovariotomy through the Vaginal Method during Pregnancy.

The vaginal method was valuable for the ablation of tumours of the ovaries complicating pregnancy, as the abdominal wall remained intact, which was of particular importance during pregnancy. When using the speculum of Professor Ott it was possible to operate by the vaginal method even on tumours situated above the superior brim, complicating adhesions being no contra-indications to the vaginal method. Posterior colpotomy was to be preferred to anterior, as the pedicle especially, thanks to the lighting of Professor Ott, could always be tied with security. The vaginal method was especially advantageous in the last months of pregnancy because of the possibility of avoiding any lesion of the abdominal wall.

Dr. G. VERBOFF (St. Petersburg) read a paper on

The Vaginal Route in Cases of Pregnancy Complicated by Cancer of the Uterus.

It was very easy to separate the pregnant uterus from the neighbouring organs, evidently because the tissues were very loose in the pregnant woman. The size of the pregnant uterus was no obstacle to the removal, because through the route of an anterior incision the uterus could be gradually emptied and removed by "morcellement." If it were possible to operate vaginally on the non-pregnant uterus, in cases of complications of pregnancy by cancer it was also easier, and this operation was to be preferred to the method through the abdominal wall, because here it was especially important to prevent the abdominal cavity from being soiled by the secretion of the cancerous tumour. Therefore it could not be understood why certain authors did not accept this route in the complication of pregnancy by cancer, and did not use the less dangerous way of vaginal extirpation.

Dr. JACOBSON (St. Petersburg) read a paper on

The Value of Colpotomy in the Treatment of Extra-uterine Gestation.

The proper treatment of extra-uterine gestation was the removal of the ovum, which led to the cessation of all symptoms. Together with the treatment of abortion the cause must be also treated by conservative and radical operations of the adnexa. The operation of choice was colpotomy, preferably the posterior operation, but under the condition of being acquainted with the technique of lighting. Anterior colpotomy should be used only in tumours situated immoveably in front of the uterus. Colpotomy attained its purpose as well as laparotomy, but with less danger for the patient. The good results of the operation gave the right to operate on every case of extra-uterine gestation. Laparotomy in the early stages of the extra-uterine gestation should be abandoned and preference given to the vaginal methods. Laparotomy was indicated only in cases of later extra-uterine gestation and in some cases of acute hæmorrhage into the abdominal cavity.

Dr. SITZINSKY (St. Petersburg) read a paper on

The Lighting of the Cavity of the Puerperal Uterus.

The lighting of the cavity of the puerperal uterus was most complete with the use of Professor Ott's specula in the inclined position of the uterus. The lighting during the treatment of the infected cavity of the puerperal uterus permitted operation with the same facility as in an infected open wound. If the uterus were ruptured the lighting permitted a decision to be made in every case as to the method to be followed.

Dr. KIPARSKY (St. Petersburg) read a paper on the Vaginal Route in the Treatment of the Neoplasms of the Uterus, in which he stated that its advantage in cases of cancer uteri was proved by a large number of recoveries with a minimum of cases of an immediate death and the maximum of lives saved.

FIFTH SESSION.

Presidents of honour: Dr. SLAVTCHEFF (Sophie) and Dr. WINTER (Königsberg).

Dr. MARKOVSKY (St. Petersburg) read a paper on

The Vaginal Route in the Treatment of Lesions of the Adnexa.

Indications: Proliferation or inflammatory cysts of the ovaries if it were evident that there were no large and solid adhesions with the parietal peritoneum or with the organs situated above the superior brim of the pelvis causing insufficient mobility as a consequence of anatomical and pathological conditions. Colpotomy was the natural operation in the treatment of intraligamentary cysts, and was very easy also in the treatment of the inflammatory lesions of the ovaries and tubes, with serous or purulent contents unilateral or bilateral, with or without adhesions.

Dr. SOBOLEFF (St. Petersburg) read a paper on

Removal of the Appendix in the Course of the Vaginal Interventions.

The method of lighting the abdominal cavity enabled an examination of the vermiform appendix in the course of a colpotomy. The removal of the appendix as an accessory operation in the course of colpotomy was quite possible, and gave good results in cases where the appendix and the neighbouring tissues were not infiltrated and could be pulled into the lower pelvis (operation of Professor Ott, April 26th,

1906). The peritoneal intestinal adhesions could be liberated without great difficulty with the aid of Ott's specula.

Dr. FUETH (Cologne) read a paper on

Vaginal Amputation of the Corpus Uteri.

In cases of hæmorrhage which could not be cured by usual methods, he believed that the best operation was that of Rieck—i.e., the vaginal amputation of the corpus uteri. The advantages were: the rapidity of the operation, the slight loss of blood, and the certainty of securing the vessels. There was no necessity to remove the cervix, the time of the operation was greatly shortened, and the abdominal cavity did not remain open for any length of time.

Dr. BECKMANN (St. Petersburg) read a paper on

Metreurysis and Vaginal Cæsarean Section as a Method of Delivery in Eclampsia.

Last year in the Obookhov Hospital of St. Petersburg he had employed early delivery by means of the vaginal Cæsarean section in cases of eclampsia and had had a mortality of only 12·4 per cent. The operation was performed seven times; it was not dangerous and presented no technical difficulties.

Dr. KROEMER (Greifswald) and Dr. D. OTT (St. Petersburg) communicated a paper on What are the Causes of the Better Results obtained by the Vaginal Method Compared with Abdominal Laparotomy?

A discussion upon the papers followed.

Dr. FALGOWSKI on the basis of 32 unpublished cases believed that the vaginal route was suitable for the treatment of the adnexa. He operated by the vaginal method also in cases of early extra-uterine gestation and even of small intra-ligamentary tumours; the sterilisation with the removal of the tubes was executed easily and was efficacious.

Dr. SELLHEIM preferred Cæsarean section in the majority of adnexal cases, especially if the pelvis was elevated; he used the incision of Pfannenstiel and spinal anæsthesia. To prevent infection, for the provisional isolation of the region of the operation of the abdominal cavity he recommended an aseptic sponge enveloped in a compress and put between two other compresses. If the case was a suspicious one and it was necessary to drain the abdominal cavity, instead of a sponge a bag filled with gauze (like that of Mikulicz) should be employed.

Dr. JAYLE (Paris) was a convinced partisan of laparotomy; he considered that the vaginal route should be reserved only for cases which were not suitable for the high operations as a consequence of some exceptional conditions.

Dr. VAN DE VELDE was against the employment of the instrument of Bossi, the use of which he had discarded. He now used the method of Bonnaire, and if the orifice commenced to tear he preferred colpohysterotomy.

Dr. A. MARTIN believed that such an extended analysis of the question of the vaginal route as had been made by the Congress could not remain without fruitful results.

Dr. MACEIEWSKI (St. Petersburg) was opposed to ventroscopy as a method which might introduce infection, bruise the tissues, and infect the ligatures of the vessels.

Dr. WINTER (Königsberg) read a paper on

Intra-uterine Intervention in the Infected Puerperal Uterus.

On the ground of a bacteriological analysis he had come to the following conclusions. If indifferent germs were present the time of delivery might be shortened, but if the bacteria were harmless delivery should be delayed until easy manipulation was possible. If hæmolytic streptococci were found, the best practice was to abstain from every operative intervention and only to try to shorten the delivery until it would be possible to finish it with proper precautions. He believed it to be more prudent to leave the streptococci in an intact tract than to produce wounds or bruises. He hoped that the time would come when by early diagnosis and by the isolation of infectious cases it would be possible to perform an operation even in cases of placental polypi, in septic abortions, and in septic fever during delivery.

Dr. LE FILLIATRE read a paper upon

The Adhesions of the Epiploon and the Bowels to the Abdominal Wall as a Consequence of Laparotomies for Intervention on the Uterus and its Adnexa.

The epiploic adhesions, pure or accompanied by intestinal adhesions to the scar of the abdominal wall as a consequence of laparotomies, often passed without being recognised, and were the cause of diagnostic errors, as in three cases observed by himself. These adhesions were causes of very different accidents which might necessitate surgical intervention according to their nature. Some of these cases simulated appendicitis and some resembled salpingitis. It was highly important to take into consideration the epiploic adhesions in all the cases where a patient who had been the subject of a laparotomy presented abdominal troubles simulating appendicitis or an affection of the lower pelvis. Consequently to prevent such complications and to avoid the necessity of a second operation on a patient, he recommended excision of the epiploon partially or totally each time when (after having opened the peritoneum) it was met in the field of operation.

Dr. ABADIE (Oran) read a paper on the Advantages of Uterine Hemisection in Hysterotomy for the Removal of Bilateral Affection of the Adnexa (the operation of J. L. Faure), which was followed by a paper on Histological Investigation of the Prophylactic Methods against Gonorrhœa by Dr. CRÉDÉ-HOERDER.

MONDAY, SEPT. 26TH.

As on Saturday, demonstrations were given from 9 to 10 A.M. on this day.

Professor OPITZ showed: (1) A Uterus with a large Cancer of the Cervix, together with Placenta Prævia, Removed through the Suprapubic Cæsarean Section; (2) a Uterus Removed by Laparotomy after Lacerations of the Cervix due to Bossi's Dilator; (3) Kidneys with Pelvis attacked by Lesions which resembled Tuberculosis under the Microscope, but did not contain Bacilli; and (4) two cases of Cancer of the Bladder (during the operation it was necessary to remove a rather large part of the bladder).

Dr. IVANOFF (Moscow) showed Preparations of the Pelvis exhibiting Dislocation of the Muscular Fibres entering into the Musculature of the Uterus.

Dr. ROSNER showed some instruments.

SIXTH SESSION.

Presidents of honour: Dr. JACOBS (Brussels) and Dr. VAN DE VELDE.

The question before the Congress at this session was the Compared Value of Different Methods of Operation in the Treatment of Dislocations and Deviations of the Uterus.

Dr. VAN DE VELDE read a paper on

The Comparative Value of Various Operative Methods in Retroflexion of the Uterus.

He stated that operative correction of retroflexion (version) of the uterus should fulfil as completely as possible the following conditions:—1. Simplicity in performance and reduction of the dangers of the operation to a minimum. In cases where it had been impossible beforehand to ascertain (with certainty) the absence of adhesions or other complications, these disorders might be recognised during the operation and the appropriate treatment applied. 2. Restoration as nearly as possible to the normal position. 3. If the trouble which existed before the operation was not sufficiently alleviated the indications and not the operation itself should be blamed. 4. The generative functions should not be interfered with in any way. In the absence of complications the possibility of conception should not differ from the normal. 5. The improved position of the uterus was only fully manifested when no relapse followed subsequent pregnancy and labour. He classified the operations as follows:—1. Operations on the uterus itself. 2. Operations which fastened the body of the uterus in front (vagino-fixation, ventro-fixation, indirect fixation, ventro-fixation of the round ligaments, vagino-fixation of the round ligaments, inguinal fixation of the round ligaments, subperitoneal shortening of the round ligaments). 3. Operations advised to fasten the cervix backwards. 4. Operations on the adjacent parts only. The attempts to obliterate the pouch of Douglas deserved full recognition, and plastic operations on the perineum and vagina were in many cases supplementary and necessary operations. As the results of present experience he recommended inguinal fixation in cases devoid of complications; indirect ventro-fixation or a combined (indirect and direct) inferior vagino-fixation in women who may become pregnant; and direct vagino-fixation or ventro-fixation for sterile women. The periodical Gynæcological Congress could appropriately organise this work. The Congress held in St. Petersburg might decide to constitute an international commission of five members who should be authorised to distribute the work amongst themselves, adding to their number, if necessary; a task which involved

the observation and publication of all notable cases; collecting and methodically arranging materials; instituting a fruitful discussion and, as soon as sufficient material was collected, making a communication thereof at a session of the next congress.

Dr. ILJIN (St. Petersburg) read a paper on

Section of the Perineum in the Median Line during Labour.

The different contemporaneous methods of protection of the perineum during labour could not prevent rupture. A large number of ruptures even if sewed up did not give a complete recovery because the tissues were lacerated and contused. The only method of escaping such lesions of the muscles was perineotomy. Whilst sewing together the lips of the wound after perineotomy it was necessary to take into consideration the normal anatomical relations of all the tissues, especially of the muscles. Therefore the separated muscles should be united by separate sutures.

Dr. EBERLIN (Moscow) read a paper on

The Value of Alexander's Operation in the Treatment of the Retrodeviations of the Uterus according to 130 Clinical Observations.

Of all the practical methods of treatment of mobile retrodeviations of the uterus the most rational was the operation of Alexander, because it was safe, its results were stable, and the clinical effect was good. *Conditio sine quâ non* of the success of this operation and of its immediate and remote effects was good technique, which consisted especially in isolating the round ligament from the fascia transversa and in shortening it sufficiently. The points against the operation, the difficulty of technique and the possibility of an inguinal hernia following, diminished its value but little.

Dr. SCHAABACK (St. Petersburg) read a paper on

The Immediate and Ultimate Results of the Operative Treatment of the Prolapsus of the Uterus.

The reconstitution of the floor of the pelvis by an extended colpoperineorrhaphy gave the most permanent results in all degrees of prolapsus of the uterus and vagina. It was also the safest operation because it gave a mortality of only 0·2 per cent. compared with a mortality of from 3 to 4 per cent. from other operations, and was free from post-operative complications which so often followed other methods. To prevent a future rupture of the perineum in the next labour (55 per cent.) prophylactic perineotomy according to Professor Ott must be made.

Dr. JACOBSON read a paper on the Restitution of the Pelvic Floor as an Operative Method in the Cure of the Prolapsus Ani, and was followed by Dr. DUETZMANN (Berlin) with a paper on the Treatment of Retroflexio Uteri by Vagino-vesico-fixation and Consecutive Labour.

Dr. ALEXANDROFF (Smolensk) read a paper on

The Shortening of the Basis of the Broad Ligaments as a Method of Operation for Retro-versio-flexion of the Uterus.

The broad ligaments of the uterus with the muscular elements placed in the basis of the ligaments had an important value in retaining the uterus and played an independent part. Whilst shortening and sewing together the cardinal ligaments the uterus was put up to the normal height, and whilst pushing the neck of the uterus backwards in the direction of the sacrum a normal position was given.

A discussion upon the points brought forward in the various papers followed.

Dr. FALGOVSKI insisted on the importance of a systematic study of the operations for prolapsus with special attention to the lesions of the bladder (cystoscopy). The operation of Alexander Adams had no influence on the bladder; it did not produce herniæ, and was therefore preferable to other operations. It could be applied even to adhesions after they had been removed by a vaginal incision.

Dr. SELLHEIM believed that retroflexion of the uterus seldom required a particular treatment; prevention was more important.

Dr. FUETH considered the operation for retroflexion necessary only if there were complaints. Patients should not be told that they had this anomaly as it was likely to produce a false conception of their disease.

Dr. DUETZMANN did not agree with the objections to the vagino-vesico-fixation. He had operated on more than 600 cases and had obtained equally good immediate as well as remote results. In 29 cases after this operation he observed labour without complications.

Dr. MACIEWSKI disagreed with the views of Dr. Iljin.

Professor OPITZ supported the proposition of Dr. Van de Velde to form a commission for the analysis of the question of the treatment of the abnormal position of the uterus, and spoke on the question of prolapsus and its anatomical causes.

Dr. KNORRE, Dr. SCHAABACK, and Dr. VAN DE VELDE also took part in the discussion.

SEVENTH SESSION.

President of honour: Dr. WETHERILL (Denver, Colorado).

Dr. JAWORSKI (Warsaw) read a paper on Metrorrhagia of Syphilitic Origin; Pains in the Uterus. He had observed eight cases of obstinate hæmorrhage which did not yield to any treatment, and he considered the cause to be sclerosis of the vessels of the uterus.

Dr. J. W. BALLANTYNE (Edinburgh) read a paper on Eclampsia and its Management: a Comparison of Methods. The general result of his observations had been to strengthen his belief in the efficacy of medical and minor surgical means of treatment applied as far as possible before the supervention of labour.

Dr. JAYLE (Paris) read a paper on Vulvar Sclerosis and Kraurosis Vulvæ. The most common cause of kraurosis was ovarian castration. In women who had undergone no operation, he believed that the disease was due to some atrophic lesion of the ovaries. Removal of the ovaries was not sufficient in itself to cause kraurosis.

A paper by Dr. RINGLEB (Berlin, Charlottenburg) on the Progress of Cystoscopy, was followed by one by Dr. RADWANSKA (Cracow) on the Treatment of Vaginitis and Endometritis.

Dr. LE FILLIATRE read a paper on the Advantages of Spinal Anæsthesia. He preferred, he said, to make the puncture between the last lumbar and the first sacral vertebræ; he injected 0·01–0·05 of cocaine—i.e., 0·5–2·5 c.c. of the 2 per cent. solution, with the patient in a particular position. He had used the method more than 2000 times in eight years.

Papers followed by Dr. ABADIE, on Rachianæsthesia; Dr. AARONS (London), on the Use of Pituitary Extract in Obstetrics and Gynæcology; Dr. RIVIÈRE, on the Value of Physicotherapy in Gynæcology; Dr. MEIER (Berlin), on Hydatid Cysts; and Mrs. ABADIE (in collaboration with Dr. ABADIE), on the Importance of Wassermann's Reaction in the Diagnosis of Gynæcological Affections.

TUESDAY, SEPT. 27TH.

From 9 to 10 A.M. demonstrations were given.

Dr. KOPTEFF (St. Petersburg) gave a Demonstration of a Metreurynter and of the Method of its Application.

The following instruments, microscopic preparations, &c., were shown:—Dr. VON SCHRENCK (St. Petersburg): A Pessary for the treatment of Prolapsus Uteri. The pessary is introduced bent in two directions. Dr. BONDY (Tübingen): Microscopic Preparations of a case of Actinomycosis. Dr. SITZINSKY: Three Pieces of the Wall of the Uterus in Metritis Desiccans. Dr. KOOZMIN (Saratov): Photographs of Four Cases of Extra-uterine Gestation operated on by him in the gynæcological department of the Zemstvo Hospital of the Saratov province. Dr. GAUSS (Freiburg): An Instrument for the Compression of the Aorta.

EIGHTH SESSION.

President of honour: Dr. ABADIE.

Dr. FRAENKEL (Breslau) described a new series of experiments which confirmed his opinion that the corpus luteum is an organ which regulates the cyclic modifications of the uterus.

Dr. OKINTCHITZ (St. Petersburg) read a paper entitled "Which Elements of the Cellular Tissue of the Ovary can be considered as Glandular Tissue?" The cells of the "cumulus oöphorus" should be regarded as glandular tissue. They fulfilled a complicated chemical function by bringing the nutritive matter to the cell of the ovule and by eliminating the products of metabolism.

A paper by Dr. BELOFF (Kharkoff) on the Rôle of the Secretion of the Yellow Bodies (Corpora Lutea) of the Ovaries was followed by one by Dr. SCHLANK (Cracow) on Clinical and Experimental Investigations on the Care of the Umbilical Cord in the New-born. He had used the method

of Gauss. He cut the cord between two forceps, putting a special pair of pincers quite near the skin, and, severing the umbilical cord, put on an aseptic bandage. The results were excellent.

Dr. NEUGEBAUER (Warsaw) read a paper entitled, "A Contribution to the Study of the Gemellar Isochronic Heterotopic Gestation. This was followed by a paper by Dr. FALGOVSKI (Posen) on Acute Relaxation of the Uterus during Narcosis by Inhalation. In four cases he had seen a sudden relaxation of the non-gravid uterus during profound narcosis. He considered that it was due to the paralysis of the centres which regulated the tension of the muscular tissue of the uterus.

Dr. KAKOOSHKIN (St. Petersburg), in a paper on the Septum Vaginæ from the Anatomical and Clinical Points of View, said that median sagittal septum vaginæ was not a rare complication. The septum was very rich in blood-vessels which had sometimes a cavernous form, and were the cause of hæmatomata and profuse hæmorrhages in pregnancy. The septum should be treated like a neoplasm: it should be totally extirpated.

Dr. IVANOFF (Moscow) read a paper on the Construction of the Muscular Layer of the Broad Ligaments of the Uterus.

In the discussion which followed Dr. STRASSMANN considered that the paralytic state of the uterus, according to Dr. Falgovski, was not proved.

NINTH SESSION.

President of honour: Dr. SELLHEIM.

Dr. DAVIDSON (Kieff) read a paper entitled "A Contribution to the Study of the Operative Treatment of Uterine Myomata." This was followed by a paper by Dr. SNEGIREFF (Moscow) on Electro-cardiographic Studies in Gynæcology.

Dr. KAKOOSHKIN read a paper on Experimental Observations on the Perforability of the Uterine Wall. He had studied the resistance of the uterine wall to perforation by a sound and had found that the force necessary for this purpose was 2088 grammes. In 3 per cent. of the cases where the peritoneum was very strong it was necessary, in order to make a complete perforation, to add a complementary force of 1285 grammes. The perforability of the uterine horns was greater than that of the fundus. The uterus was more easily perforated in nulliparæ than in multiparæ.

Dr. ABADIE read a paper on the Treatment of Congenital Absence of the Vagina by Transplantation of the Bowel. He described a case and analysed the advantages and the features of his method compared with those of Baldwin. Intestinal transplantation gave better results than the method of Thiersch, but was more difficult. The choice depended not only on the physician but also on the patient, to whom the condition should be explained.

A paper by Dr. MODLINSKY (Moscow) on the Sacral Route in Gynæcology and Surgery was followed by the last paper of the Congress by Dr. MONTOYNONT (Madagascar), the subject being Gynæcology in Madagascar.

It was decided that the next International Congress should be held in Berlin in September, 1912, when the question of the Comparative Value of Different Methods in the Treatment of Dislocations and Deviations of the Uterus will be discussed. The Proceedings of the Congress will appear in due course.

THE CHOLERA EPIDEMIC.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

DURING the past summer the Russian Empire has been, for the seventh year in succession, the scene of a severe epidemic of cholera, and the disease has spread—no doubt from that country—to Germany, Austria, Hungary, Italy, Roumania, Turkey in Europe, and Asia Minor. The present, indeed, would appear to be the most widely spread epidemic of cholera that has been seen since the years 1892–1895. It will be useful to follow in some details the course the disease has followed during the past few months.

Cholera in Russia.

It will be recalled that (as described in my letter which appeared in THE LANCET of March 26th last, p. 891) cholera had, so far as was known, ceased to be epidemic in all parts of Russia some time during the month of January. The last known case seems to have occurred on Jan. 17th (29th). For nearly three months no cases or deaths from the disease were reported from Russia. In April, however, cholera reappeared in the Ekaterinoslav government (which borders the Sea of Azov), and a little later it was reported from the Vitebsk government (bordering on Polish Russia). In the former 38 cases with 7 deaths occurred between April 4th and 21st. The following are the weekly returns for the whole of Russia, beginning with April 18th (this and all dates subsequently mentioned in connexion with the Russian epidemic are according to the Old Style, unless otherwise stated):—

Week ending	April	24th	...	21	cases,	4	deaths.
,, ,,	May	1st	...	48	,,	17	,,
,, ,,	,,	8th	...	74	,,	42	,,
,, ,,	,,	15th	...	160	,,	65	,,
,, ,,	,,	22nd	...	317	,,	143	,,
,, ,,	,,	29th	...	840	,,	305	,,
,, ,,	June	5th	...	2,304	,,	830	,,
,, ,,	,,	12th	...	4 093	,,	1,436	,,
,, ,,	,,	19th	...	3,322	,,	1,611	,,
,, ,,	,,	26th	...	4 636	,,	1,237	,,
,, ,,	July	3rd	...	9.308	,,	4,211	,,
,, ,,	,,	10th	...	18,316	,,	8,310	,,
,, ,,	,,	17th	...	18,376	,,	8 327	,,
,, ,,	,,	24th	...	26,625	,,	11,541	,,
,, ,,	,,	31st	...	30,610	,,	13,674	,,
,, ,,	Aug.	7th	...	19 688	,,	9,659	,,
,, ,,	,,	14th	...	12,510	,,	6,376	,,

The above figures are the latest "corrected" figures available here. The following are "uncorrected" figures, and will certainly be increased when the exact numbers are later made known:—

Week ending	August	21st	...	9843	cases,	4405	deaths.
,, ,,	,,	28th	...	7559	,,	3557	,,
,, ,,	Sept.	4th	...	4412	,,	2071	,,

The totals for the whole country from the beginning of this year's epidemic down to August 14th (27th) are officially put at 154,445 cases and 74,723 deaths. This is, therefore, as stated above, by far the most severe cholera epidemic that has occurred in Russia since the early "nineties" of last century. It will be of interest to give a brief summary of the behaviour of cholera in Russia and adjoining countries during the past few years.

In 1903 Russia was apparently free from the disease. In 1904 cholera caused a somewhat severe epidemic in the Caucasus, and spread to some extent along the Volga and its branches, as far as Ufa, Nijni Novgorod, and Yaroslavl. In 1905 the disease broke out in the Polish provinces in the autumn and continued to prevail until the early months of 1906. Only 445 cases and 220 deaths were registered. From February, 1906, to July, 1907, there was a cholera-free interval. A widespread but not very severe epidemic then followed, beginning on the Volga and extending to most parts of European and Asiatic Russia; nearly 12,000 cases and 6000 deaths were reported. The disease also crossed the frontiers of Asiatic Turkey and Persia. In 1908 the disease reappeared in the Volga Valley in July, and again spread widely in all parts of the Empire; the infection again invaded Persia, and that year's pilgrimage to the Hedjaz suffered severely from the disease. In 1909, with only a very brief interval, cholera continued to prevail in Russia; during the year over 20,000 cases and over 9000 deaths were recorded. The disease also spread into Holland and East Prussia.

Returning to the present outbreak from this very hurried summary of the past, it will be observed that this year's epidemic reached its highest point in the week ending July 31st (August 13th), when as many as 30,610 cases and 13,674 deaths were registered. Since then there has been a rapid decline, but the infection is still active and still widely spread.

The course of the epidemic seems to have been as follows. In April the disease was present only in the governments of Ekaterinoslav, Vitebsk, and Baku, and an isolated case had occurred in Moscow. For St. Petersburg the published evidence is very conflicting. Suspicious cases occurred there during January and February. From April 11th to 24th as many as 52 suspicious cases were seen and several more in

the following week and throughout May. But the beginning of this year's epidemic there is put down to June 7th. In May cholera had appeared in the south-central governments of Kharkof, Mogilef, Kief, Poltava, Taurida, Tchernigof, Kherson, Voronezh, Tambof, Minsk, and the Don Territory, and in the provinces of the Kuban and the Terek in the Caucasus. The towns of Kertch, Odessa, and Rostof-on-Don were also invaded in that month. In June and July nearly all the remaining European governments were infected; the disease had spread to the northerly governments of Archangel, Vologda, Viatka, and Perm, to the Caucasian governments of Daghestan, Stavropol, Kars, Erivan, Tiflis, Elizavetpol, and Kutais; isolated cases had occurred in Finland and in the ports of Revel and Riga; and in these months or early in August cholera had been reported from the Central Asiatic Provinces of Transcaspia, Syr Daria, Akmolinsk, Uralsk, and Turgai, and from the governments of Tomsk and Tobolsk in Siberia.

The intensity of the epidemic varied, of course, widely in different parts of the country. The provinces from which the highest figures have been received (i.e., the highest absolute figures; I am unable at this moment to give the figures in proportion to the population) have been the following:—

Kuban province	21,849 cases,	14,072 deaths.
Don Territory	19,538 ,,	9,031 ,,
Ekaterinoslav government	15,406 ,,	6,964 ,,
Voronezh ,, ...	7,973 ,,	3,403 ,,
Samara ,, ...	7,330 ,,	3,277 ,,
Kherson ,, ...	7,016 ,,	2,965 ,,
Stavropol ,, ...	5,457 ,,	2,741 ,,
Taurida ,, ...	4,145 ,,	2,055 ,,
Saratof ,, ...	4,049 ,,	1,575 ,,
Kief ,, ...	3,978 ,,	1,474 ,,
Kharkof ,, ...	3,938 ,,	1,709 ,,
Terek province	3,871 ,,	1,643 ,,
Kursk government	3,595 ,,	1,570 ,,
Kostroma ,, ...	3,325 ,,	1,561 ,,
Poltava ,, ...	2,942 ,,	1,168 ,,
Kazan ,, ...	2,888 ,,	1,303 ,,
Tambof ,, ...	2,843 ,,	1,371 ,,
Simbirsk ,, ...	2,464 ,,	1,055 ,,

The figures in the above table represent in each instance the total cases and deaths reported down to the week ending August 14th (27th), the latest "corrected" figures available. It will be seen that the epidemic has been most active in the southern provinces of European Russia, in the valley of the Volga, and in the northern Caucasus. At the other end of the scale, only single cases of cholera have been reported from the northerly governments of Archangel, Olonetz, and Pskof; in Finland but two cases were reported (respectively from Kuopio and Nyslott); in the port of Riga only 2 cases with 1 death occurred, and in that of Revel there was but 1 case of the disease. The figures for Central Asiatic Russia and Siberia may be given separately as follows:—

Transcaspia	84 cases,	52 deaths.
Syr Daria province	46 ,,	25 ,,
Uralsk ,, ...	33 ,,	13 ,,
Turgai ,, ...	85 ,,	43 ,,
Akmolinsk ,, ...	245 ,,	144 ,,
Tobo'sk government	86 ,,	40 ,,
Tomsk ,, ...	32 ,,	6 ,,

Cholera in Germany.

The only appearance of cholera in Germany during the present year seems to have been the occurrence of two cases of the disease in Spandau, near Berlin. One occurred on August 25th, the other on August 27th. The latter died in hospital. Several other suspicious cases were seen, but the bacteriological evidence was always found to be negative. On the other hand, on August 31st and on Sept. 1st, 2nd, and 6th cholera-resembling bacilli were found in the intestinal contents of four of the "contacts" who had been isolated in the hospital at Spandau.

Cholera in Austria.

On June 21st it was reported that a fatal case of suspected cholera had occurred at Podvolokziska, on the frontier of Galicia, in a person who had arrived from Rostof on Don. On the 25th of the month the appearance of cholera on the Galician frontier was officially confirmed from Vienna, without further details. Nothing further was heard of cholera in Austria until August 26th, when 2 suspicious cases were reported from Vienna itself; 1 had been isolated on the 23rd and the other on the 24th; 1 died. In both apparently there was bacteriological evidence that the disease was cholera. The source of the infection was not known. Between August 23rd and Sept. 17th, 7 cases of the disease with 2 deaths occurred in Vienna. The latest bulletin states that between Sept. 18th and 24th there were 2 cases of cholera in Vienna and 1 at Brünn, making a total from the beginning of 9 cases in Vienna and 1 at Brünn, with 3 deaths out of the 10 cases.

Cholera in Hungary.

On Sept. 14th it was officially made known here that the following 5 cases of cholera had occurred in various parts of Hungary. On August 28th a woman had fallen ill on the tug *Regensburg*, on the journey from Vienna to Poszony; she died on the 31st. On August 26th a man had died from cholera at Mohacz. On the 30th a woman died at Voeroesmarton. On Sept. 6th a sailor died at Goenyoe. Finally, on the 7th a man died from the disease at Nagybacs. All these places are situated along the banks of the Danube, and it was officially stated that no connexion could be traced between the different cases. On Sept. 19th it was reported that in addition to the above 5 cases 16 others had occurred in Hungary down to the 17th. Finally, between Sept. 17th and 24th as many as 49 cases with 23 deaths were registered.

Cholera in Italy.

On August 18th news was received here of the appearance of cholera in the Italian province of Bari; the first telegram stated that 30 cases with 20 deaths had already occurred. The next day's telegram stated that 26 fresh cases and 22 deaths had been recorded on the 18th. It was at first believed that the infection had been imported by a batch of Russian passengers who had arrived at Bari on August 1st, after stopping at Trani; Bari itself was not at first infected, but Trani was, as also the ports of Barletta, Bisceglie, and Margherita di Savoia. It has not as yet been made clear whether the above-mentioned Russian passengers were in truth the means of introducing the infection to the country. However introduced it soon spread to the province of Foggia. Down to August 22nd 125 certain cases, 6 suspicious cases, and 58 deaths had been registered in the province of Bari, and 59 certain cases with 32 deaths in that of Foggia. On the 22nd there were 29 cases and 25 deaths in the two provinces; on the 23rd 18 cases and 18 deaths; on the 24th 17 cases with 15 deaths; on the 25th 26 cases and 14 deaths, and on the 26th 29 cases and 18 deaths. The subsequent bulletins have been imperfect and irregularly received. It appears, however, that between August 26th and Sept. 20th there were 93 cases and 66 deaths at Barletta, 60 cases and 22 deaths at Molfetta, 49 cases and 28 deaths at Trinitapoli, 29 cases and 14 deaths at Cerignola, 20 cases and 11 deaths at Andria, 19 cases and 19 deaths at Trani, 21 cases and 18 deaths at Margherita di Savoia, 14 cases and 8 deaths at San Ferdinando, 5 cases and 5 deaths at Spinazzola, 4 cases and 3 deaths at Canosa, 2 cases at Bitanto, 3 cases and 1 death at Ortanova, and 1 case and 1 death at Corato.

All the above places are situated on the south-east shores of Italy. More recently cholera has appeared on the opposite shores—at Naples. The information about the outbreak there is conflicting. As early as August 20th it was reported from Rome that, according to rumour, 4 suspicious cases had occurred in Rome and 1 at Naples, but these rumours were not confirmed. In the middle of September it was persistently reported that the disease was epidemic in Naples, but the existence of the disease was equally persistently denied by the Italian authorities. On Sept. 17th the Italian Ministry for Foreign Affairs issued an official bulletin declaring that no case of cholera had been seen in Naples to that date, that the mortality of the town was below the average, that there were several cases of gastro-enteritis in the town but they were few in number and in no way suspicious, that in some of them only coli bacilli were found, but that in some others a cholera-resembling bacillus had been found, which, however, did not agglutinate in a dilution of 1 in 40 or 1 in 50, and that consequently all suspicion of the existence of cholera could be put aside. In spite of this, however, some Italian papers continued to publish cholera bulletins for Naples, declaring that some 10, 15, or 20 cases were occurring there daily. The

authorities continued to deny that cholera existed, though the Turkish, American, Spanish, and other Consuls were delivering "foul" bills of health. Finally, at the end of September it was officially declared that 2 cases of cholera and 1 death had occurred in Naples.

Cholera in Bulgaria.

Up to the present the only mention of cholera in Bulgaria has been the report of a death on Sept. 8th from what was believed to be the disease on board a Hungarian ship at Samovit, a Bulgarian port on the Danube.

Cholera in Roumania.

As in Hungary and Bulgaria, so in Roumania, cholera seems to have been mainly confined to the valley of the Danube. Only very few cases have occurred. On Sept. 7th there was a (suspicious) death of a woman at Galatz, and on the 17th a suspicious case at Tchernavoda, 64 kilometres from Kustendje; but in both these cases the bacteriological evidence was negative. On the 19th a suspicious case occurred at Corabia; on the 13th and 19th two suspicious cases were seen at Braila, and one of these was confirmed by the results of bacteriological investigations. Finally at Galatz a guard on the landing-stage of the Italian line of steamers died from cholera on Sept. 12th, and here also there was bacteriological confirmation of the nature of the disease.

Cholera in Asiatic Turkey.

With cholera prevalent along the Russian shores of the Black Sea, in the ports of Sevastopol, Odessa, Taganrog, Theodosia, Nikolaiefsk, Kertch, Poti, and Batum, it is not surprising that the infection has spread to the parts of Asia Minor adjoining Russian territory. Since the middle of July several imported cases of the disease have been seen on steamers or sailing ships arriving from Russian ports at Trebizond, Surmené (close to the Turko-Russian frontier), Sinope, Kavak (at the entrance of the Bosphorus), and other ports. In the town of Trebizond the earliest cases were seen on Sept. 16th, when 6 cases with 2 deaths were recorded in four different houses. The disease soon spread here; on the 18th there were 6 cases among the reservists newly called to the colours, and on the 21st there were 12 cases in the local prison. The epidemic has since prevailed in the town, among the reservists, and in the prison, and down to Sept. 25th there had been in all 127 (registered) cases and 64 deaths. Of the cases 40 had occurred in the prison.

The infection appears to have passed the land frontier between Russia and Turkey towards the end of July; on the 20th of that month 2 sudden deaths occurred in a batch of 210 persons crossing the frontier at Keutek. It was not, however, until a month later that the disease spread in the neighbouring *vilayet* of Erzerum. On August 22nd 3 cases and 2 deaths were recorded in the village of Vekil Khan, three days' journey from Erzerum, and 2 suspicious cases in Erzerum itself. In the week ending August 26th 21 cases and 13 deaths had been recorded in the *vilayet;* in the week ending Sept. 2nd there were 18 cases and 26 deaths; in that ending Sept. 9th 13 cases and 6 deaths; in that ending Sept. 16th 48 cases and 30 deaths; and in that ending Sept. 23rd 224 cases and 138 deaths. In the last two bulletins the figures relate to the *vilayets* of Erzerum and Van together. In the last bulletin the names of 23 villages are included in the list; that most severely affected was the village of Nardjan, where 130 cases of cholera with 80 deaths had occurred.

The port of Zunguldak, on the Black Sea—important as being the port for the large coal mines of Eregli (Heraclia)—has recently become infected. Since Sept. 28th 10 cases have occurred there among arrivals from Constantinople and inhabitants of the port.

Mention may also be made of a suspicious death at Basra, near the head of the Persian Gulf, but there is as yet no confirmation of the belief that this was a case of cholera.

Cholera in Constantinople.

Apart from rumours and unconfirmed cases, the first case of undoubted cholera in this city (confirmed bacteriologically) was declared on Sept. 19th; the illness had apparently begun on the 13th and the patient (a woman) died on the 17th. This case occurred in the low-lying and specially insanitary quarter of Haskeui, near the tip of the Golden Horn. Down to Oct. 4th there have been in all 69 cases with 34 deaths. The principal "foyers" of the disease have been at Haskeui, and in the equally low-lying and insanitary quarters of Cassim Pasha and Fundukli. The cases have, however, been very widely scattered through all, or a greater part of, this large city, which, with its suburbs, spreads from the Marmara to the Black Sea, and includes the Asiatic shores of the Bosphorus and (for some distance) of the Marmara. From three to seven cases are still being reported daily, and it may be suspected that slight cases occur which do not come to the knowledge of the authorities. It may be noted, however, that the total mortality in the city during the past few weeks has not shown any marked tendency to rise.

Cholera in Persia.

Early in August cholera appeared in the Russian port of Astara on the Caspian Sea, but it was not till the middle of the month that the Persian port of Astara became infected. At Ardebil the disease broke out in July and continued to prevail through August; the returns from this town have been very imperfect, but between August 1st and 10th there were 66 cases and 29 deaths among its inhabitants, who number about 30,000. In July the governor of Ardebil reported that cholera existed at Hassan Barough, Niase, and Nir, on the Ardebil-Tabriz road; on July 19th it was reported from Dare-Djaz and Kelat-i-Nadiri in the province of Khorassan. On August 15th cholera was present in Sorab, a town of 10,000 inhabitants on the Ardebil-Tabriz road, and for some time from 10 to 15 cases occurred there daily. The disease was also reported from Nedjan and Velazguerd, near Ardebil, and from Djounta, near Sorab. Until later and fuller reports are received it is impossible to know exactly the extent of Persian territory invaded by the disease, or the intensity of the epidemic in different portions of that territory.

Constantinople, Oct. 5th.

THE QUATERCENTENARY OF JOANNES CAIUS.

ON Thursday, Oct. 6th, the quatercentenary of the birth of John Caius was celebrated at Gonville and Caius College, Cambridge, of which College he was the second and most munificent founder. The occasion was made largely a medical one, and the justification for this was abundant. Although the University of Cambridge has always kept before her as her ideal a broad academic training rather than a professional equipment, and although this is distinctly the ideal of those at present in authority over Gonville and Caius, yet the second founder of the college was a great physician and president also of a great medical corporation. John Caius in his day was an embodiment of the widest learning as well as an exponent of professional wisdom; he was a fine scholar and had, indeed, once been a professor of Greek; but it was as a court physician that he made the large fortune which enabled him to re-establish the ancient Gonville Hall on lordly lines, and to incorporate with it his new college of Caius. Caius was, moreover, not only President of the Royal College of Physicians of London, but was at one time physician to St. Bartholomew's Hospital, residing within the precincts of the hospital; it was therefore particularly fitting that to the commemoration of his 400th birthday the Master and authorities of his college should invite to take part in the proceedings the official heads of the medical profession. Science in general, indeed, as well as that of medicine, was well represented at the commemoration, as is sufficiently shown by enumerating some of the distinguished guests who were present at Cambridge on the occasion: Professor Sir Clifford Allbutt, F.R.S. (Regius Professor of Physic in the University of Cambridge), Sir W. Allchin, Sir T. Barlow, F.R.S. (President of the Royal College of Physicians of London), Rev. Dr. Bonney, F.R.S. (President of the British Association), Dr. J. B. Bradbury (Downing Professor of Medicine in the University of Cambridge), Mr. H. T. Butlin (President of the Royal College of Surgeons of England), Sir Francis Champneys (chairman of the Central Midwives Board), Sir William Church, Sir Anderson Critchett, Professor Howard Marsh (Master of Downing College and Professor of Surgery in the University of Cambridge), the Bishop of Ely, Dr. W. Ewart, Dr. J. Kingston Fowler, Sir A. Geikie

(President of the Royal Society), Dr. F. de Havilland Hall, Professor Jackson, O.M., F.B.A. (Regius Professor of Greek in the University of Cambridge), Dr. F. G. Kenyon, F.B.A. (Director of the British Museum), Sir Joseph Larmor (secretary of the Royal Society), Dr. P. W. Latham, Dr. E. Liveing, Dr. Norman Moore (senior physician to St. Bartholomew's Hospital), Dr. J. A. Ormerod, Professor W. Osler, F.R.S. (Regius Professor of Medicine in the University of Oxford), Professor W. Ridgeway, F.B.A. (Disney Professor of Archæology), Dr. Sandys, F.B.A. (Public Orator), and the Vice-Chancellor of Cambridge University (Dr. R. F. Scott, the Master of St. John's College).

The proceedings commenced with a service in the Caius Chapel, at which the Rev. Dr. SWETE, Regius Professor of Divinity in the University of Cambridge and Fellow of the College, delivered an excellent address on the fruitfulness of an alliance between scholarship and medicine as exemplified in the persons of St. Luke and John Caius. Following upon the service came the commemoration banquet, at which 162 persons sat down in hall, under the presidency of the Rev. E. S. Roberts, Master of the College, who was supported by the Bishop of Ely (Dr. F. H. Chase, formerly President of Queens' College), the Vice-Chancellor, the Master of Corpus, the Master of Magdalene, the Master of Sydney-Sussex, the Public Orator of the University, and the Mayor of Cambridge. The rest of those present were mainly past and present members of the College, among whom were a large proportion of Doctors of Medicine in the University. After dinner the grace and anthem composed by Dr. Charles Wood, Mus. Doc., and a Fellow of the College, was rendered by the choir from the new gallery of the dining-hall, to which ladies were admitted to hear the speeches.

The MASTER having proposed the loyal toasts, Dr. J. VENN, the President of the College, delivered an eloquent address to the memory of John Caius. Speaking without notes and seldom pausing for word or phrase, Dr. Venn told the moving story of Caius' career in a manner which must have left its imprint on all those who heard him. He described the boundless generosity of the man, his courage in adversity, his unceasing intention to benefit those who, urged by private feelings or by political and religious motives, rebelled within the walls of the college which he had founded against the rules of the man to whom they owed everything.

The *Carmen Caianum* was then sung by the choir, after which the MASTER proposed the health of "The Guests." He took the toast out of its usual order in signification of the fact that those with whose names he coupled it were present at a commemoration banquet to John Caius in circumstances of particular aptness, for Sir Thomas Barlow was President of the College where Caius had once presided, and Dr. Norman Moore was senior physician to the hospital where Caius had once lived and worked. Sir THOMAS BARLOW, in a brief reply, alluded in terms that were very acceptable to all his hearers to the theory of training which the University of Cambridge had set before herself in her desire to abate none of her industry in respect of the old learning, while resolving also to keep abreast with the new learning. Dr. NORMAN MOORE, in an admirable speech, reminded the audience that Caius was the first of three great founders of homes of learning, all of whom were members of the medical profession, the other two being John Radcliffe, whose devises to Oxford led to the foundation of the Radcliffe Library, the Radcliffe Fellowships, and the Radcliffe Infirmary, and Sir Hans Sloane, whose bequest of his splendid collections to the nation in return for a moderate sum of money was the origin of the British Museum. Sir ARCHIBALD GEIKIE then proposed prosperity to the University of Cambridge, whose services to science he as President of the Royal Society was happy to acknowledge, and this toast was fitly coupled, not only with the name of the Vice-Chancellor of the University, but with that of Professor Henry Jackson, the Regius Professor of Greek. Here, again, the reply was invited from a particularly appropriate person, seeing that the feast was in honour of Caius, for there is no doubt, not only from known historical facts, but also from the evidence of manuscripts that Caius was a very good Greek scholar. The toast of "Prosperity to the College" having been proposed by the Bishop of ELY, was replied to by the MASTER

Good weather, good speaking, and great hospitality combined to make the commemoration a notable event in the medical world.

THE CORONERSHIP FOR THE CENTRAL DISTRICT OF THE METROPOLIS.

IN connexion with the appointment of a successor to Dr. G. Danford Thomas, the late coroner for the Central District of the metropolis, the London County Council on Oct. 11th, at the first meeting after the summer recess, received a report from the Public Control Committee recommending the rearrangement of the coroners' districts in North London. Under the Coroners Act, 1892, a vacancy must be filled within three months of its occurrence, so the new appointment must be made not later than Nov. 5th. In consequence of the large size of the central coroner's district the committee in 1891 decided that the district should be divided into two at a suitable opportunity, division to be made as nearly as possible on the basis of the number of inquests. Owing to the Council being in recess when the present vacancy occurred time would not permit of the necessary steps being taken before Nov. 5th to effect an alteration of the boundaries of the district. The committee proposed, therefore, that a coroner should be appointed to the district as at present constituted but at a salary based upon the work in the portion of the district which would be left to him after the boundaries had been rearranged.

The Council in 1895 passed a series of resolutions directed to improving the conditions under which the duties of coroners were performed. It was then pointed out that in London there were ten coroners whose duties and salaries varied considerably; that it appeared probable that a smaller number would suffice under new arrangements; and that it would be more dignified if the position of coroners approximated more nearly to that of stipendiary magistrates with districts about equal in amount of work, and salaries not dependent on the number of inquests held, and with proper courts, including a clerk and other officials necessary in a court of inquiry. The recent Departmental Committee largely endorsed this view, and a Bill now before the House of Commons put the matter in a definite shape. As to the new appointment, therefore, regard should be had to the possibility of alteration of the law.

The committee had come to the conclusion that the arrangement foreshadowed in 1891 was hardly desirable, and that instead of forming an additional district certain modifications should be made in the coroners' districts north of the Thames. The boroughs of Paddington and St. Marylebone should be transferred from the Central to the Western District, and the portion of Finsbury known as the parish of St. Luke should be transferred from the North-Eastern to the Central District. This rearrangement would divide the work about equally between the four coroners' districts north of the Thames, and the work of each district, the committee thought, would not be beyond the powers of a coroner who devoted his whole time to the duties of his office. The new Western District would comprise Hammersmith, Fulham, Kensington, Chelsea, Paddington, and St. Marylebone, with an aggregate population of 839,024, a total of deaths in 1909 of 11,220, and an average number of inquests during five years of 1035. The new Central District would contain Hampstead, St. Pancras, Islington, Holborn, and Finsbury, with a population of 831,903, a total of deaths of 11,927, and an average number of inquests of 1118.

With regard to remuneration, the committee stated that it had been the practice to calculate a coroner's salary upon the basis of a definite sum per inquest and the average number of inquests held, but the committee proposed that a departure should be made from this practice. Hitherto the basis had been 30*s.* per inquest until the salary reached £1350, but no salary went beyond that amount unless the average number of inquests held on a basis of 21*s.* per inquest would produce a higher salary. The earlier basis of £1 6*s.* 8*d.* per inquest, with an allowance of 9*d.* a mile for travelling expenses, had been reverted to in the case of some of the districts. The committee recommended that the salary of the new coroner for the Central District should be £1250 a year, this amount to be regarded as including £250 to meet the expenses of the office, comprising payment of deputy, provision of office accommodation, clerical help, &c. If the Council made the proposed rearrangement of districts, additional work would fall upon Dr. C. Luxmoore Drew, the coroner for the Western District, whose salary should be raised from £1126 to £1400.

In fixing these salaries the committee had in mind the possibility that an amendment of the law might provide for the pensioning of whole-time coroners without requiring them to contribute by a deduction from their salaries. The adoption of the scheme outlined would effect a saving of nearly £800 a year.

The committee recommended that a petition be presented to the King praying him to order the alterations proposed in the coroners' districts; that notice thereof be given to the coroners, and that they be consulted before the petition is presented; and that an advertisement be issued inviting applications for the appointment to the Central District.

When the report came before the Council a member asked the Chairman whether persons who had written to councillors asking for their votes in connexion with the appointment would be disqualified under the standing orders of the Council.

The Chairman replied that if such letters had been written they were highly improper, but as the vacancy had not been advertised, technically no breach of the standing orders had been committed.

The Council adopted the Public Control Committee's proposals and decided to advertise for applications for the post of coroner for the Central District at a salary of £1250 a year.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County Borough of Birkenhead.—At midsummer of last year the population of this borough was estimated at 120,955; the birth-rate for the year was 30·9, and the death-rate 15·9 per 1000 in each case. The infantile mortality was 122 per 1000 births. In connexion with this latter rate Dr. R. Sydney Marsden discusses the question of adopting the Notification of Births Act, and he concludes that as such adoption would entail considerable expense, and as voluntary work and advice are now being carried out, it is a question whether the advantages gained would be equivalent to the annual outlay required. In support of his opinion he selects certain towns in the North-West district which have adopted the Act, since in his view only towns in this district can be fairly compared with Birkenhead. These towns are Burnley, Preston, Bolton, Stockport, St. Helens, Liverpool, and Bootle, and of these the last three have much higher birth-rates than the remainder. As regards infantile mortality, Dr. Marsden shows that in nearly every year since 1900 the Birkenhead birth-rate is lower than all the others, except Bolton; and he observes that although the Notification of Births Act has been adopted in all of them, their returns do not show any advantage to have accrued therefrom over Birkenhead—i.e., their rates are still higher than those of Birkenhead. But Dr. Marsden does not tell us the dates at which the Act in question was adopted in the several towns mentioned; and all that it appears can be said is that in the majority of these towns—all, in fact, except St. Helens—there was a substantial decrease in 1909 in the infantile mortality-rate, and in several the actual rate of decrease was greater than that of Birkenhead. The problem really has to be settled by considering the fall in each town in relation to its own rate rather than by any comparison between the several towns. But it is clear that excellent work is being done in Birkenhead by the health visitors.

The States of Guernsey.—Dr. H. Draper Bishop estimates the population of Guernsey at 44,145, the birth-rate for 1909 being 22·94 and the death-rate 11·62 per 1000 in each case. The infantile mortality was 109·6 per 1000 births, a rate which was only beaten in 1896 and 1903, in both of which years there was a wet and comparatively cold autumn. Two cases of human diphtheria are stated to have been contracted from a puppy, the nasal discharge manifesting diphtheria bacilli, while one case is attributed to a sick cat. There were four cases of enteric fever which occurred one after the other in, or in connexion with, the same house and which appear to have been due to personal infection. It seems, however, that they were locally attributed to witchcraft. There was during 1909 a severe outbreak of enteric fever at St. Brieuc in France, and as a result the Royal Court of Guernsey, at the instance of the Board of Health, passed an ordinance forbidding the importation of oysters and other molluscs from France. Dr. Bishop expresses the hope that this ordinance may be made a permanent one. This is a method of dealing with impure shell-fish which might be considered by our own Parliament. Arrangements have now been made by the States for granting compensation to the owners of cattle slaughtered for tuberculosis, and a mutual insurance company has been formed towards the same end. There were 756 Guernsey cattle exported during 1909, of which number 703 were sent to the United States. Of this total only four reacted to the tuberculin test. Nineteen cattle were slaughtered during 1909 owing to their having tuberculosis, and in each instance the remaining animals of the herd were tested by the States veterinary surgeon. Dr. Bishop thinks that bovine tuberculosis should soon become extinct in Guernsey. The most pressing need of the island from a sanitary standpoint is the provision of a satisfactory water-supply.

The City of York.—Dr. Edmund M. Smith reports that an arrangement was made with the registrar of the local cemetery in 1907 to forward weekly returns of the particulars concerning each still-birth sent for burial, and during 1909 there were 107 such notices received. When necessary, further inquiries were made. Of the total number in question 73 were notified for burial by medical practitioners, 32 by registered, and 2 by unregistered midwives. Referring to the subject of cancer, Dr. Smith insists upon the need for the education of the public regarding the earlier symptoms of this disease, and he observes that if women would appreciate the possible gravity of abnormal discharges, and at once seek medical advice, much of the mortality from uterine cancer might be avoided. York is one of the relatively few towns which still obtain their water-supply from a river through the agency of a private water company. In this case the water is taken from the Ouse about a mile above the centre of the city, the water being first screened and submitted to settlement in subsiding reservoirs, then passed through a mechanical filter, and finally through sand filter-beds. It does not appear that any prolonged storage prior to filtration is provided for, but the filtrate is regarded as yielding satisfactory bacteriological results.

Borough of Scarborough.—Dr. John Knight, basing his estimate upon the number of occupied houses, places the population of Scarborough at 41,480, instead of 42 156, as estimated by the Registrar-General. The birth-rate, 18·8 per 1000, showed an increase on the 17·7 for 1908. Scarborough, as regards its births, occupies an unenviable position in the matter of illegitimacy, which is attributed largely to the excessive proportion of single women at conception ages. For the period 1876–1905 the illegitimate births per 1000 births in Scarborough amounted to 84, as compared with 44 for England and Wales, and in the year 1909 the local illegitimate rate was no less than 107 per 1000 births. The infantile mortality rate evinces a very gratifying fall since the commencement of the present century, and the rate for 1909 was only 72 per 1000 births. This rate, as Dr. Knight points out, is the more satisfactory in that it obtains notwithstanding the marked rise in the illegitimate birth-rate referred to above—that is to say, there has been a larger number of illegitimate lives, and, as is well known, it is among such lives that the death-rate usually reaches a very high figure. In these circumstances it is refreshing to find Dr. Knight, while according due credit to the various agencies at work, cordially rendering unto Nature that which is her due, and admitting that the cool wet summer was hostile to the prevalence of epidemic diarrhœa. He rightly points out, however, that similar weather conditions have frequently occurred before since 1876 without any corresponding reduction in the infantile mortality rate. Among the steps taken to reduce the infantile mortality in Scarborough is a voluntary system of notification of births of such thoroughness that it has not been deemed desirable to adopt the Notification of Births Act, 1907. There are also mothers' meetings where the babies are weighed and the results recorded, and a "babies' welcome" club, in which expectant mothers are encouraged to save to meet the expenses of their confinement. It had been decided to set aside part of the accommodation at the isolation hospital for the education of tuberculous patients, but an epidemic of scarlet fever prevents the realisation of the proposal.

City of Cardiff.—Cardiff, which has an estimated population of nearly 200,000, derives its water from upland gathering grounds some 35 miles from the city, and the water as supplied to the inhabitants manifests an excellent degree of purity, B. coli in 40 cubic centimetres being generally absent. All the meat consumed in the city is slaughtered in the municipal slaughter-houses, there being no private slaughter-houses, and in order to improve the standard of meat inspection two new inspectors specially conversant with meat have been appointed to act under the direction of the veterinary surgeon. The Notification of Births Act, 1907, was adopted in 1908, and Dr. Edward Walford reports that it has been very useful as a means of reducing infantile mortality. Two health visitors have been appointed, and six centres have been established in suitable parts of the city to which mothers are invited to bring their babies for weighing and advice. Special attention has also been paid to the milk-supply of the town, and powers have been obtained from Parliament under a local Act towards this end, including what are known as the model milk clauses which, *inter alia*, enable the medical officer of health to take samples of milk either within or without the city. Voluntary notification of pulmonary tuberculosis has been in force in Cardiff since 1901 and the number of notifications received in 1909 was 171. In connexion with this scheme educational measures have been practised and arrangements made for gratuitous bacteriological examination. Dr. Walford evidently favours the establishment of a tuberculosis dispensary, and it looks as if one may shortly be in operation. The question of erecting a municipal crematorium has on several occasions been before the sanitary authority, but no decision has yet been arrived at.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 7741 births and 4163 deaths were registered during the week ending Oct. 8th. The annual rate of mortality in these towns, which had been equal to 13·0 and 13·3 per 1000 in the two preceding weeks, declined last week to 12·8. During the 13 weeks of last quarter the death-rate in these towns averaged 11·8 per 1000, corresponding with the rate that prevailed in the third or summer quarter of last year. In London the death-rate last quarter, calculated on the probably over-estimated population, did not exceed 11·0 per 1000. The lowest reported annual death-rates in these 77 towns last week were 3·7 in King's Norton, 6·5 in Handsworth, 6·6 in West Bromwich, and 7·1 in Tottenham; the rates in the other towns ranged upwards to 18·9 in Stoke-on-Trent, 19·0 in Rochdale, 20·7 in Sunderland, and 21·8 in Burnley. In London the reported death-rate last week did not exceed 12·3 per 1000. The 4163 deaths registered in the 77 towns last week showed a decline of 168 from the number returned in the previous week, and included 497 which were referred to the principal epidemic diseases, against numbers declining from 720 to 537 in the six preceding weeks; of these 497 deaths, 311 resulted from diarrhœa, 53 from measles, 49 from whooping-cough, 42 from diphtheria, 21 from scarlet fever, and 21 from enteric fever, but not one from small-pox. The mean annual rate of mortality from these diseases in the 77 towns last week was 1·5 per 1000, against rates ranging from 2·2 to 1·6 in the six preceding weeks. No death from any of these epidemic diseases was registered last week in East Ham, Hornsey, Reading, Bournemouth, Handsworth, Hastings, or Great Yarmouth; the annual death-rates therefrom ranged upwards, however, to 3·9 in Burnley and in Huddersfield, 4·2 in Grimsby, and 4·4 in Bury. The deaths attributed to diarrhœa in the 77 towns, which had declined in the five preceding weeks from 527 to 364, further fell last week to 311; in the several towns, however, they caused annual rates ranging upwards to 2·6 in Blackburn and in Preston, 3·4 in Burnley, 3·5 in Bury, and 4·2 in Grimsby. The 53 fatal cases of measles showed an increase of 21 upon the low number in the previous week, and included 18 in London, 11 in Liverpool, 5 in Manchester and Salford, and 3 in Leeds. The 49 deaths from whooping-cough also showed an increase; this disease was most fatal in Rotherham, where the 3 deaths were equal to an annual rate of 2·4 per 1000. The 42 deaths referred to diphtheria showed a further increase upon the numbers in recent weeks, and exceeded the number in any previous week of this year; they included 13 in London and its suburban districts, 4 in Stoke-on-Trent, and 3 in Leeds. The fatal cases of scarlet fever, which had been 27 and 25 in the two previous weeks, further declined last week to 21, including 2 in Bristol and in Sheffield and 3 in Salford. The deaths referred to enteric fever, which had increased in the four preceding weeks from 12 to 38, declined again last week to 21, of which 7 were registered in London and 3 in Hull. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased in the seven preceding weeks from 1423 to 1653, had further risen to 1706 on Saturday last; 245 new cases of this disease were admitted to these hospitals during the week, against 201, 210, and 249 in the three preceding weeks. The 1148 deaths from all causes in London last week included 165 which were referred to pneumonia and other diseases of the respiratory system, showing a decline of 13 from the number in the previous week; they were 7 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 33, or 0·8 per cent., of the deaths registered in the 77 towns during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, Nottingham, Leicester, and in 50 other smaller towns; the 33 uncertified causes of death in the 77 towns last week included 7 in Liverpool, 4 in Birmingham, and 2 each in London, St. Helens, Rochdale, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 845 births and 521 deaths were registered during the week ending Oct. 8th. The annual rate of mortality in these towns, which had been equal to 13·0, 13·6, and 13·7 per 1000 in the three preceding weeks, further rose to 14·4 in the week under notice. During the 13 weeks of last quarter the death-rate in these towns averaged 12·9 per 1000, and exceeded by 1·1 the mean rate during the same period in the 77 largest English towns. The annual death-rates in the eight Scotch towns last week ranged from 10·2 and 11·7 in Leith and Paisley to 16·9 in Dundee and 19·6 in Perth. The 521 deaths from all causes in the eight towns last week showed a further increase of 24 upon the numbers in the three preceding weeks, and included 69 which were referred to the principal epidemic diseases, against 78, 72, and 83 in the three preceding weeks; of these 69 deaths, 40 resulted from diarrhœa, 14 from diphtheria, 8 from whooping-cough, 5 from scarlet fever, and 2 from "fever," but not one either from measles or small-pox. The mean annual rate of mortality from these epidemic diseases in the eight towns last week was equal to 1·9 per 1000, the rate from the same diseases in the 77 English towns being only 1·5 per 1000. The deaths attributed to diarrhœa in the Scotch towns, which had been 45, 47, and 51 in the three preceding weeks, declined last week to 40, but included 23 in Glasgow, 4 in Dundee and in Paisley, and 3 in Aberdeen and in Leith. The 14 deaths from diphtheria corresponded with the number in the previous week; 8 occurred in Glasgow and 4 in Edinburgh. The 8 fatal cases of whooping-cough also corresponded with the number in the previous week, including 4 in Glasgow and 3 in Greenock. Three of the 5 deaths from scarlet fever occurred in Glasgow, as did both the deaths referred to "fever"; of the latter, 1 was certified as enteric and 1 as cerebro-spinal meningitis. The deaths referred to diseases of the respiratory system in the eight towns, which had been 64 and 61 in the two preceding weeks, increased to 72 in the week under notice, and exceeded by 13 the number in the corresponding week of last year. The causes of 12, or 2·3 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, the mean annual rate of mortality during the 13 weeks of last quarter averaged 16·3 per 1000; the mean rate during the same period did not exceed 11·8 in the 77 largest English towns and 12·9

in the eight principal Scotch towns. The annual death-rate in Dublin during the week ending Oct. 8th was equal to 19·5 per 1000, against 18·8, 21·4, and 20·2 in the three preceding weeks; this rate, however, exceeded by 7·2 per 1000 that which prevailed last week in London. The 151 deaths from all causes in Dublin last week showed, however, a further decline of 5 upon the numbers in the two preceding weeks, and included 20 which were referred to the principal epidemic diseases, against 29 and 30 in the two previous weeks; these 20 deaths were equal to an annual rate of 2·6 per 1000, the rate from the same diseases last week in London being only 1·1. The 20 deaths from these epidemic diseases in Dublin included 12 from diarrhœa, 2 each from diphtheria, enteric fever, and whooping-cough, and 1 each from measles and scarlet fever. The fatal cases of diarrhœa in Dublin, which had been 21 and 27 in the two previous weeks, declined to 12 last week. The causes of 3, or 2·0 per cent., of the deaths registered last week in Dublin were not certified, corresponding with the number in each of the two preceding weeks. In Belfast during last week 200 births and 94 deaths were registered. The deaths showed a further decline from the numbers returned in recent weeks and were fewer than in any previous week of this year. The annual rate of mortality in the town, which had been equal to 16·3 and 14·0 per 1000 in the two preceding weeks, further declined last week to 12·5. The 94 deaths from all causes in Belfast last week included 9 which were referred to the principal epidemic diseases, against 18, 17, and 12 in the three preceding weeks, and were equal to an annual rate of 1·2 per 1000; of these 9 deaths, 7 resulted from diarrhœa, and 1 each from measles and whooping-cough. The fatal cases of diarrhœa in Belfast, which in the six preceding weeks had declined from 29 to 7, were again 7 last week. The causes of all but one of the 94 deaths registered in the town last week were duly certified either by a registered medical practitioner or by a coroner.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeons: A. R. H. Skey to the *Inflexible*, on recommissioning; and M. P. Jones to the *Hogue*. Surgeons: C. G. Sprague to the *Inflexible*, on recommissioning; G. A. S. Hamilton to the *Jupiter*, additional, for disposal in the Portsmouth Subdivision of the Home Fleet; and J. P. Berry to the *Orontes*.

ROYAL ARMY MEDICAL CORPS.

Major John J. C. Watson, C.I.E., retires on retired pay (dated Oct. 8th, 1910).

Lieutenant-Colonel John Battersby is placed temporarily on the half-pay list on account of ill-health (dated Oct. 2nd, 1910).

Captain Denis J. F. O'Donoghue retires receiving a gratuity (dated Oct. 12th, 1910).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant George F. Randall is seconded for service under the Colonial Office (dated August 13th, 1910).

DEATHS IN THE SERVICES.

Brigade-Surgeon-Lieutenant-Colonel Robert Nasmyth MacPherson (A.M.S. retired), recently at Weymouth, in his seventy-third year. Shortly after qualifying in 1864 he entered the army as assistant-surgeon, being first attached to the Royal Field Artillery and afterwards the Army Medical Staff. He had a considerable amount of foreign service and served 15 years in India. He was at one time medical officer in charge of the military hospital at Portsmouth.

ROYAL NAVAL HOSPITAL, HASLAR.

The prizes to the newly-entered surgeons who have been under instruction at the Royal Naval Hospital, Haslar, were distributed on Oct. 7th by Admiral Sir John Durnford, president of the Royal Naval College, Greenwich. Among those present was the Director-General of the Medical Department of the Royal Navy, Sir James Porter, K.C.B. After Inspector-General T. D. Gimlette had read a very satisfactory report the prizes were distributed. Surgeon W. H. King won the gold medal, Surgeon H. E. R. Stephens the silver medal and prize for analysis, Surgeon C. F. O. Sankey the prize for hygiene, and Surgeon J. S. Ward the prize for tropical medicine. Admiral Sir John Durnford, in addressing those present, said the provision and organisation of the services in peace and war was of considerable importance to the nation and of deep interest to the naval medical and nursing services. The question as to whether any steps were necessary to render the national forces more efficient had been considered by a committee with which he had been connected and certain recommendations had been unanimously agreed upon. Those recommendations had not yet been made public, but he hoped that effect would soon be given to them.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The first place in the October issue of this journal is given to an article by Major C. E. Pollock on Florence Nightingale in regard to her work in connexion with the military hospitals in the East in 1854–55. By reason of her sex and the nature of the work to which she dedicated her life she is associated in the public mind with a very large amount of sentiment which is apt to obscure the real woman, and Major Pollock has done a useful work in making clear the wonderful organising capacity of her brain. The article, which will be read with great interest, contains the rules which Miss Nightingale laid down for her nurses, as well as letters written from Scutari and Balaklava, and, as Major Pollock points out, show what a complete grasp Miss Nightingale had obtained of the whole subject of military nursing by females after little more than six months' experience. The article concludes:—

> More fortunate than many other great public benefactors, Florence Nightingale was permitted to see the fruits of her teaching in the establishment of numerous training schools for nurses, and the elevation of nursing from an occupation followed by elderly women of no education into a scientific profession under the patronage of the highest ladies in the land. It may not be generally known that the red uniform cape worn by the ladies of the Queen Alexandra's Imperial Military Nursing Service is modelled on that originally introduced by Florence Nightingale for the nurses whom she took with her to Scutari. This cape may therefore be regarded as a memorial to the great founder of military nursing.

BRITISH RED CROSS AND TERRITORIAL NURSING NOTES.

On Oct. 5th Lord Basing presided at a meeting of the Hampshire branch of the British Red Cross Society, which was held at Odiham, when it was decided to form a voluntary aid detachment.

Voluntary aid detachments are about to be formed in Carlisle.

The Mayoress of Westminster and Lord Cheylesmore have issued on behalf of the Red Cross Society an appeal to large employers of labour for assistance in raising in Westminster voluntary aid detachments to afford supplementary aid to the Territorial Medical Service in national emergency.

Deputy-Inspector-General Thomas Edward Henry Williams, R.N. (retired), has been appointed Resident Examining Officer for Recruiting Duties at Bristol.

THE BRITISH RED CROSS SOCIETY.—A public meeting was held on Oct. 7th at Exeter in connexion with the Exeter division of the British Red Cross Society. The Mayor presided, and there was a large and influential gathering. Sir Frederick Treves gave an interesting address on the Red Cross Society, and said that he could not imagine any project that appealed more to patriotism than to offer aid to sick and wounded fellow-countrymen in the event of this country being invaded.

THE NORTH DEVON INFIRMARY, BARNSTAPLE.—The annual meeting of the subscribers to the North Devon Infirmary was held on Oct. 4th under the presidency of the Mayor. The medical report stated that during the past year the in-patients numbered 754, against 815 in the previous 12 months. 2614 out-patients were treated, compared with 2904 in the preceding year. The financial statement showed a deficit of £371. The committee stated that through the generosity of the late Mr. W. Allen a complete new dental department had been opened in connexion with the infirmary, and added that through want of funds it had been reluctantly decided to close one of the wards last March.

Correspondence.

"Audi alteram partem."

THE MEANING OF THE AUDIBLE SOUNDS IN MITRAL STENOSIS.

To the Editor of THE LANCET.

SIR,—It may seem presumptuous on my part to criticise Dr. Alexander Morison's learned and closely argued paper contained in your issue of Oct. 8th, yet whilst agreeing in the main with his views, I hesitate to accept some of his conclusions as to the meaning of the second and third sounds which form part of the triple apical rhythm in mitral stenosis. He maintains that the second of these three sounds is produced by a left ventricular extra-systole, and that the third is in reality the second cardiac sound with a "bruit admixture." These are the conclusions which I would venture to discuss, but before doing so some preliminary remarks seem necessary.

In the first place I cannot regard the triple apical rhythm or a presystolic bruit as evidence of mitral stenosis, for although these sounds are commonly heard in children of 5 or 6 years, the "button-hole" mitral valve is practically unknown at this age. I do not doubt that stenosis does take place in many of these young children if they live long enough, but in early life the triple apical rhythm and presystolic bruit are evidence not of stenosis but of roughened and perhaps incompetent mitral valves.

In the second place, I would deprecate the use of the term "reduplicated second sound" to describe the second and third sounds which form part of the apical triple rhythm. For were they indeed due always to asynchrony in the closure of the aortic and pulmonary valves respectively, as the term implies, they should be audibly divided at the base of the heart (at all events in a child) and not audible only "in a limited area—namely, the inner apex or, more precisely, in an area usually extending from the apex to the left edge of the sternum and upwards as far as the fourth rib."

Of course, reduplication of the second sound *may* be audible at the apex, but if it is really due to asynchrony in closure of the aortic and pulmonary valves, it must also be heard at the base, whereas in the cases to which I refer the triple sound is heard only at the apex. A further reason for disputing that the second and third sounds of the triple apical rhythm are reduplicated cardiac second sounds is that they are quite unlike each other in character, whereas the divided sounds produced by asynchrony in closure of the aortic and pulmonary valves respectively are precisely similar in timbre and duration.

The simplest explanation of the triple apical rhythm is that the first of the three sounds is the heart's first sound (often accompanied by a systolic bruit), the second is the ordinary normal cardiac second sound due to sudden tension of the aortic and pulmonary valves, whilst the third is a diastolic bruit produced at the mitral orifice. This diastolic bruit is direct and not regurgitant, for it is never conducted outside the apex of the heart into the axilla. In quality it is never short and sharp like the second of the three sounds, but is always softer and more prolonged than the second sound, and its duration often varies almost from hour to hour.

When the heart is beating forcibly and rapidly this diastolic bruit becomes shorter, but, as Dr. Morison says, "it remains a long sound as compared with the second." When cardiac action is slow and languid the bruit may be prolonged throughout the diastolic period until it becomes a typical rumbling and crescendo presystolic murmur.

Dr. Morison's suggestion is that the second of the triple apical sound is "a left ventricular extra-systole, so closely approximated to the preceding systole as to be *graphically* unregistrable but nevertheless audible." I cannot help thinking that he weakens his suggestion by admitting that this ventricular extra-systole is "graphically unregistrable," for whilst sharing his caution in drawing inferences from graphic records, I should expect that our delicate modern instruments of precision would afford some evidence of a ventricular extra-systole in a cardiogram. Surely a muscular contraction sufficient to produce a sound so audible as this is, would reveal some indication of its presence on a tracing.

Again, were it due to a ventricular extra-systole one might expect it to be accompanied at times by a systolic bruit, considering that the triple rhythm is as a rule associated with mitral disease. But to my ear at all events, the second of the triple sounds is always clear, short, and sharp, and in all respects resembles the normal second cardiac (aortic and pulmonary) sound. I find it difficult, moreover, to believe that close approximation of an ordinary and an extra-systole prevents the latter from being graphically recorded, for in my experience the interval between them is of definite and appreciable duration.

The third sound of the triple apical rhythm Dr. Morison regards as the second cardiac sound with a "bruit admixture." I quite agree as to the bruit, and in the case which forms the text of Dr. Morison's paper no doubt there was a genuine reduplication of the second cardiac sound heard both at base and apex, and obscured at the latter site by a diastolic bruit. But for reasons already mentioned I am disinclined to believe that the third sound of the triple apical rhythm is only a reduplicated second cardiac sound. I regard it as a diastolic bruit which in early stages of mitral disease may become temporarily presystolic, and eventually may become permanently so. In some cases I admit that it may be associated with a reduplicated second sound, but as a rule it is a diastolic mitral bruit and nothing else.

Dr. Morison is, I believe, correct in attributing the bruit to a weak flow of blood from auricle to ventricle through a diseased (but not necessarily stenosed) mitral valve, and when it becomes prolonged and presystolic in character the sound is probably due partly to suction of blood through the diseased mitral valve by the expanding ventricle, and partly to the final impulse given by systole of the auricle to its contents.

The meaning of the triple apical rhythm is not merely of academic or physiological interest. Asynchrony inclosure of the aortic and pulmonary valves is of minor importance as compared with mitral disease. Hence my object in writing is rather to protest against the common teaching that the second and third sounds of the apical triple rhythm are to be regarded merely as reduplicated second cardiac sounds than to take exception to Dr. Morison's views which necessarily bear more weight than my own.

I do not dispute that true reduplication of the second cardiac sounds may be audible at the apex, but such cases need careful discrimination from those in which the third sound of the triple apical rhythm is a mitral diastolic bruit.

I am, Sir, yours faithfully,

LEONARD GUTHRIE.

Upper Berkeley-street, W., Oct. 8th, 1910.

EFFICIENT VENTILATION AT SEA.

To the Editor of THE LANCET.

SIR,—I entirely dissent from the views expressed by the writer of the note in THE LANCET of Oct. 8th. The public are quite right in the use of fans, and no better means could be taken for relieving the discomfort of ship cabins. The chemical purity is not the only need, nor in all cases is it the first need, of ventilation. In warm, moist, stagnant air we suffer from the strain on our heat-regulating mechanism, and the movement of the air relieves this. If the writer would let me put him into my experimental chamber at 80°-85° F. (wet bulb) he would cry out for the fans to be put on, and he would neither sense nor care if the CO_2 rose, not to 0·5 per cent., as in the closest and most crowded living room, but to 4–5 per cent.! In close atmospheres we long for air and for moving air. A close day is a moist, warm day with no wind stirring. We long for wind. The common expressions of everyday life show this. All the text-book teaching is based on an ideal of chemical purity. But all the experimental evidence shows that 1 or 2 per cent. more or less CO_2 or oxygen in the air breathed makes no physiological difference. There is no evidence worth a jot that the traces of organic material found in close air are harmful. As in the case of water, the organic material is only an indicator of the number of bacteria present in the air.

When the evidence is sifted we find the claim for chemical purity (in the absence of dangerous pollutions such as CO) can be based justly on bacteriological grounds alone. We catch colds in spite of all our systems, and the open-air man as a rule does not, in spite of exposure to the same infection. Moving cool air by its cooling effect tones up the skin and nervous system, keeps us active, increases our metabolism,

the oxygen taken in, and the food later; by increasing muscular activity it aids the circulation, for the muscles pump the blood as, or even more, effectively than the heart. After muscular activity the heart is relieved and the arterial pressure kept down.

The immune properties of the blood are brought into action by an active circulation and are probably increased by a greater metabolic turnover. Open-air treatment is not a question of chemical purity of the air, but acts by increasing the metabolism, and so the vigour of the body. The cool moving quality of the air is the active agent, and it is continual exposure to such air and to active muscular exercise that we owe most of the benefit of sea and mountain holidays. The relief given by fans in an air-tight chamber at 85° F. (wet bulb) is complete, when eight men have been shut in it for 30 minutes and the CO_2 has reached 5 per cent. No fresh air is brought in, but the stagnant stale air is whirled and it cools the sweating body.

I am, Sir, yours faithfully,

LEONARD HILL.

London Hospital Medical College, Oct. 11th, 1910.

THE PROPERTY IN PRESCRIPTIONS.

To the Editor of THE LANCET.

SIR,—The views of my friend Mr. H. Wippell Gadd as to the ownership of prescriptions do not seem to me to be conclusive. I hold that a prescription is a confidential message sent to the pharmacist, instructing him how to prepare and label certain remedies, intended to bring about the cure for which the physician is engaged. I submit, therefore, that the document, being a legal warrant to the chemist to supply certain, perhaps poisonous, drugs to the patient, for which the pharmacist might otherwise be punishable by law, should, properly speaking, be retained by him.

Consider the document carefully. It is written in a tongue presumed to be unknown to the patient. It opens with a certain mystic symbol ℞, which is taken to be a contraction for the imperative "recipe," "take thou"; in other words, it is a distinct instruction addressed to a subordinate. It runs, for instance:—

℞ Morphinae acetatis ... ... gr.ss.
Pulveris colchici ... ... gr.iii.
Fiat pilula, quartis horis sumenda.
Mitte vi. folio argenteo involve.

That is, the chemist is directed to take so much morphine and so much colchicum, to make so many pills, to silver them in a certain way, and to put on a certain instruction for the patient.

It seems to be suggested that the physician's contract is to furnish a prescription to cure the malady, that therefore it is the patient's property. I submit not. The pharmacist is not an independent contractor; he acts merely as agent for the doctor. It is not for him to disclose the nature or contents of the prescription or to comment on its suitability. Neither is it for him to dispense morphine to anyone who chooses to ask for it; he must have a medical prescription—and a medical prescription is not any favourite formula of a bygone physician, copied from the books, but a definite order of an actually attendant physician for the specific patient, not for any infant or idiot. Suppose I write an order for the nurse, "Give the patient an enema of soap-and-water," is the prescription his property? Can he produce it as an authorisation at any time to any nurse to give the enema at my instructions? I submit not; and I suggest that the prescription to the chemist is on all fours with this case rather than with those from other professions which Mr. Wippell Gadd cites.

I am, Sir, yours faithfully,

J. C. MCWALTER, M.D. Brux., D.P.H., F.F.P. & S.G.,

ON THE FAILURE OF NERVE ANASTOMOSIS IN INFANTILE PALSY.

To the Editor of THE LANCET.

SIR,—We were much interested in Dr. A. Stoffel's criticism of Sept. 10th of our paper in THE LANCET of April 2nd, 1910, on the Failure of Nerve Anastomosis in Infantile Palsy. This criticism is founded chiefly on some valuable work of Dr. Stoffel published in the *Zeitschrift für Orthopädische Chirurgie*, Vol. XXV., 1910. We may therefore be pardoned for not having availed ourselves of his help, since our cases were operated upon from two to five years ago.

Two points may be mentioned in which we fear the absence of a detailed account of our cases may lead to misinterpretation. First, Mr. Murray took care that an actual severance of healthy nerve fibres was always made; we had long been aware of the necessity for this. Secondly, in Case 4, when we wrote, "the extensors of the right foot alone were paralysed," we meant to imply that the sural muscles were unaffected and not that the peroneal group (musculo-cutaneous) was free.

Dr. Stoffel's paper is largely a record of dissection results, and it still remains to be shown how far these results can be applied at the operation table. We think that to some extent this may be done, and the partial success which he has obtained in deltoid and biceps paralysis by a double nerve anastomosis—i.e., circumflex to ulnar and musculo-cutaneous to median—is gratifying. This procedure was in our mind when we stated that in our opinion too much had been attempted when dealing with cases of infantile palsy, and that a less ambitious operation might be more successful. Dr. Stoffel believes that the fibres to individual muscles retain a given position throughout a nerve trunk, and his contribution to this important question is a most careful one. We venture, however, to make three observations on this matter. 1. It is known that at least one-third of a nerve trunk may be cut without any appreciable palsy resulting. 2. That the most satisfactory demonstration of the course of nerve fibres is to be obtained by the partial section of a nerve trunk and a study of the sites of the resulting Marchi degenerations. 3. That the dissection method may, as a nerve fibre is followed up, unravel the twisted skein and so produce a deceptive appearance of the fibres lying in a given sector of the trunk.

We are, Sir, yours faithfully,

R. W. MURRAY.
Liverpool, Oct. 9th, 1910. W. B. WARRINGTON.

THE ST. JOHN AMBULANCE ASSOCIATION AND THE TERRITORIAL FORCE AMBULANCE SERVICE.

To the Editor of THE LANCET.

SIR,—As a member of the Order of St. John of Jerusalem and of its ambulance department I was much attracted and interested by the very ably written article on that Order which appeared in THE LANCET of Sept. 24th. It is but a few weeks ago that I read in the *Hospital* a paragraph in which it was asserted that the sole *raison d'être* of the Order was its ambulance department. Tradition, it may be, weighs little with some persons. To my mind, the Order, of which Sismondi wrote that a nation organised as it was could conquer the world, and Gibbon that though "they had neglected to live they had been prepared to die in the service of Christ," embodies traditions the grandeur of which can hardly be surpassed. Of such traditions, however, up-to-date education knows and recks little.

I gather that the death of Miss Florence Nightingale, who was a Lady of Grace of the Order of St. John, inspired the admirable paper to which I have referred. In the public expression of that strong national feeling to which her death gave rise I also found food for thought. If others have done splendid work in the cause of aid to the sick and wounded, the "Lady of the Lamp" was the one on whose brow in the eyes of the people the halo of heroism rested. It seemed to me that only the irony of fate could have willed that the two organisations, to which the country looks for the provision of the ambulance service of its Territorial Force, should at the moment of her decease be very much at variance. Both sent wreaths for her funeral; both were represented at the memorial service at St. Paul's; but this unanimity was merely conventional. In 1854 Miss Nightingale rescued a Secretary of State for War from the wrath of a nation exasperated by the reports of the sufferings of the sick and wounded in the Crimea. The War Office of 1910 would best repay their great debt of gratitude to Miss Nightingale by promoting peace between the "St. John Ambulance" and the "Red Cross."

Your article mentions many distinguished medical men as being members of the Order of St. John. I would fain have the privilege of selecting two of their number to act as mediators in the deadlock which is paralysing the War Office "Voluntary Aid" scheme. My selections would be

Sir Frederick Treves and Sir Arthur Conan Doyle. The latter wrote from South Africa ten years ago a most touching tribute (possibly in your columns) to the courage and devotion of the St. John Ambulance hospital orderly. The former stated at the banquet given by the Reform Club on April 30th, 1900, in honour of Sir William Mac Cormac and himself, that "there had never been a campaign in which the horrors of war had been so mitigated and the treatment of the wounded so complete" as in South Africa. To this noble work the St. John Ambulance Association contributed 2200 men, of whom about 70 died during the war.

I am, Sir, yours faithfully,

The Athenæum, Oct. 7th, 1910. A. C. YATE.

*** Since our correspondent's letter was received the War Office has entered into an agreement with the St. John Ambulance Association under which the Army Council can register St. John Ambulance Brigade and County Companies, under certain conditions, as Voluntary Aid Detachments. In this way further provision is made for the sick and wounded of the Territorial Force in case of war.—ED. L.

THE ETIOLOGY AND DIAGNOSIS OF GERMAN MEASLES (RUBEOLA).

To the Editor of THE LANCET.

SIR,—Dr. C. Beards and Mr. W. L. Goldie, in their paper on German measles, published in your issue of Oct. 1st, make mention of certain "small yellowish plaques usually on the mucous membrane behind the last molar teeth of the lower jaw," and state that "as they are occasionally present in morbilli and scarlet fever they are of little value in diagnosis." In my experience these plaques or spots are not confined to patients suffering from rubella, morbilli, or scarlet fever, but will occasionally be found in children who are in good health. They usually form a group of which the posterior are much larger than Koplik's spots, though the anterior may closely resemble them. They are of a faint orange-yellow colour.

I think it is a pity that the writers of the paper do not employ the word "rubella" instead of "German measles" or "rubeola." The term "rubella" has suffered less misuse than any other designation; its brevity makes it better than "German measles"; it raises no false idea of origin, and avoids confusion. Further, it has been adopted by the majority of writers on infectious diseases of recent years to signify the disease in question. The term "German measles" is misleading and a little cumbrous. "Rubeola" is also misleading. It has been applied to measles (morbilli), e.g., by Corlett in his "Treatise on the Acute Infectious Erythemata" (1902). This writer agrees with others in the use of the word "rubella."

I am, Sir, yours faithfully,

E. W. GOODALL.

The Eastern Hospital, Homerton, N.E., Oct. 5th, 1910.

THE TREATMENT OF THE MORPHIA HABIT BY "PANTOPON."

To the Editor of THE LANCET.

SIR,—The preparation of opium referred to by Dr. Oscar Jennings in THE LANCET of Oct. 8th as Pantopon is known in Great Britain as "Omnopon," and represents the total alkaloids of opium in the form of hydrochloric salts. The average dose is 1/5th to 1/3rd of a grain three times a day. For internal medication, tablets have been prepared consisting of "Omnopon" 1/10th of a grain triturated with sugar of milk. This form is suitable for the continuous use of "Omnopon" in suitable cases. Ampoules of 1 cubic centimetre of a 2 per cent. sterile solution of "Omnopon" are placed on the market. One cubic centimetre of this sterile solution equals 1/3rd of a grain "Omnopon." In addition to Dr. Oscar Jennings' work on "Morphinisme et Morphinomanie," other references to Pantopon will be found in *Münchener Medizinische Wochenschrift*, No. 25, 1910, (Sahli); "Therapie der Gegenwart," 1910, Book 5 (Hallervorden); *Therapeutische Monatshefte*, January, 1909 (Sahli); and *Münchener Medizinische Wochenschrift*, No. 7, 1910 (Heimann).—We are, Sir, yours faithfully,

THE HOFFMANN-LA ROCHE CHEMICAL WORKS, LTD.

COMPULSORY INSURANCE AGAINST SICKNESS IN GERMANY:

ITS BEARING ON THE MEDICAL PROFESSION.

(FROM A CORRESPONDENT.)

Industrial Conditions Leading to Compulsory Insurance.

THE introduction of steam power gave birth to those vast industries that now form a great part of a nation's assets and the developments of electricity tend to multiply those industries indefinitely. As a result of the conditions under which they work, the thousands of hands employed in manufactories and allied enterprises recently began to form a distinct body of the community at large. These workers are dependent for their livelihood on their daily wage, they have no personal interest in the fruits of their labours, and are not bound by any strong ties to a particular locality, but are free to seek their work according to momentary phases regulating demand and supply. In this they contrast with the tradesman or holder of land, however small the title to independence and ownership may be. Many workers are either not in a position or feel no inclination to save for the proverbial rainy day, and thus, when overtaken by some catastrophe, as sickness or want of employment, not only they but those dependent upon their earnings are cast upon the charity of the remainder of the community. This question marks one of our gravest social problems, all the more difficult to solve as the political element has entered largely into the minds of those actively engaged on the subject.

For some time past various countries have taken steps towards effecting a remedy in this state of affairs, and the granting of old-age pensions was the first step taken by Great Britain towards breaking with the time-honoured custom of leaving the individual subject to work out his own salvation. This may quite soon be extended by the compulsory insurance against sickness. A Government measure of this kind will naturally affect to a certain extent the interests of the medical profession, and it would be well to consider in time the points likely to be raised. As matters are at present, an agreement between a sick club or friendly society and a medical man is to all intents and purposes a purely business question, largely influenced by competition in the struggle for life. When the State, however, decides to introduce some social reform, it would be lacking in its duty towards safeguarding the interests of the whole nation it embodies by conferring benefits on a few to the exclusion of others, and it is here that the medical man's interests must be taken into consideration.

State Insurance against Sickness in Germany.

Among those countries that have already introduced State insurance against sickness, Germany, as the pioneer country, will serve as an apt illustration. The regulations regarding compulsory insurance against sickness, which are to a certain extent distinct from the insurance against accidents and the invalidity and old-age pensions, may be briefly summarised as follows:—

Every male or female person, regardless of age, whether unmarried or married, German subject or foreigner, employed in the country in any form of trade or work, receiving a salary or pay not exceeding £100 per annum, is compelled to be insured against sickness. Legally freed from this obligation are soldiers, officials, and servants of the empire, states, or municipalities, for which other provision has been made, also pharmaceutical assistants and apprentices. All persons whose income is under £100 a year may voluntarily insure themselves. The insured become members of a distinct sick club, of which many kinds are recognised. They may be divided into two classes:—1. Sick clubs composed of members belonging to the same profession or branch of trade in a certain locality. These are called local sick clubs, and each must have at least 100 members. Or the workers in a certain trade may

be insured in a trade sick club embracing all its members throughout the empire; these correspond somewhat to the trade unions. Factories, mines, and other undertakings employing over 50 workpeople may form their own sick club. 2. Municipal sick clubs, to include all those not insured in one of the above kind of clubs.

The various sick clubs are self-governing, but are under control and inspection of the Government authorities. Employers and employees participate in the management, and both parties have to contribute; one-third of the amount levied has to be paid by the employer and the remaining two-thirds are contributed by the insured person. The total contribution may not exceed 4 per cent. of the member's wages. To take a concrete example. A workman employed in a factory with a sick club levying 3¾ per cent. is earning 30*s.* a week. He will have to contribute two-thirds of the total amount levied (1*s.* 1½*d.*)—i.e., 9*d.*, and his employer 4½*d.*, a week. It may be mentioned that every sick club is compelled to possess a reserve fund representing the total annual expenditure based on an average of three years' expenses. This fund is entrusted to the authorities who have to take charge of its administration.

In case of illness of a member, the sick club has to defray all the costs of medical attendance, medicines, trusses, spectacles, &c., or of any special treatment required; for instance, a member may be sent to undergo a course of baths at some well-known resort at the club's expense. These benefits are granted for a period not exceeding 26 weeks, after which time, if the person is still incapacitated for work, the provisions of the invalidity insurance are enforced. During this time the patient may undergo treatment in a hospital, or failing this he receives sick pay from the third day of falling ill, corresponding to half his wages, but not exceeding 3*s.* a day. If the member is compelled to undergo treatment in a hospital, those dependent upon his wages for their maintenance receive half the amount he would be otherwise entitled to as sick pay. In case of death 20 times his average daily wage is paid out. Female members are entitled to full sick pay for six weeks after childbirth. The above represent the minimum that sick clubs are legally compelled to do for their members, but those in a flourishing financial condition are free to extend the scope of the benefits conferred, which usually take the form of granting free medical treatment to the uninsured dependents of the members or increase of sick pay.

The Relations of German Sick Clubs and the Medical Profession.

In order to be in a position to confer these more tangible benefits, other forms of expenditure are as far as possible cut down to the lowest figure, and this is the point upon which the interests of the medical profession and those of the sick clubs diverge. It is, in fact, the predominant question at issue to-day for the German medical man to resist the autocratic desires of the clubs, and in this respect their organisation can point to some notable successes in resisting the many attempts made to render the practitioner subservient to the wishes of the sick clubs. The clubs' aim is to introduce what may be called the "tied doctor" system, whereas the profession, and to a certain extent the members, maintain that the insured should be free to choose their medical attendant from among the whole number of those who agree to the sick clubs' terms.

It cannot be denied that the fact that some millions, who formerly postponed calling in medical attendance until the last moment, are now able to do so without having to consider the question of fees, had a material influence on the position of the medical profession. Soon, however, it became evident that the slight remuneration agreed to, mainly on the ground that it meant an assured source of income to the practitioner, was in no adequate relation to the services rendered, and led to insistance upon a fairer recompense for work and skill. It must be remembered that in most of the German States there exists a legal minimum and maximum scale of fees for professional duties. The Prussian medical tariff enumerates no less than 163 different items covering medical attendance and surgical operations of various degrees. These charges are applicable in the absence of any special agreement; the minimum charges are to be made in the case of members of charitable or State institutions, otherwise the fee is to be reckoned within the limits stated, according to the time or skill required and financial position of the patients.

The following may serve as an example of the rate of remuneration thus established:—

Some Items in the Prussian Medical Tariff.

First visit to a patient	2*s.* to 20*s.*
Every further visit	1*s.* ,, 10*s.*
First consultation at medical man's house	1*s.* ,, 10*s.*
Every further consultation	1*s.* ,, 5*s.*
(These charges include full examination and writing out a prescription.)	
A consultation over the telephone	1*s.* ,, 3*s.*
Consultation of two or more medical men, to each	5*s.* ,, 30*s.*
(Visits or consultations between 9 P.M. and 7 A.M. twice to three times the above rates.)	
Subcutaneous injections, enemata, injections into the urethra	1*s.* ,, 3*s.*
(The first three times full charge, afterwards only half, but not under 1*s.*)	
Opening a superficial abscess	2*s.* ,, 1 *s*
First simple dressing of a small wound	1*s.* ,, 10*s.*

The most usual form of contract between a sick club and a medical man is that the club sets aside a sum ranging from 3*s.* to 6*s.* per member per annum for medical attendance, and this amount is paid in full to the medical man. Sick clubs which extend medical attendance to other members of the family of the insured allow twice to three times this amount. Where several medical men participate, the total amount is divided amongst them in a variety of ways. One is that the whole sum is handed over to the local medical association, which undertakes its division among the sick club medical men, or the services rendered are divided into various classes, each being allotted a certain number of points, and the single medical man receiving his share according to the total number of points he has to his credit. Other sick clubs pay in full the lowest charges of the tariff, or have a contract whereby a 10 to 20 per cent. rebate is deducted from these charges. Another system which is adopted by the sick club of one of Germany's leading chemical works is, that every half year each member of the club is called upon to choose his medical attendant for the ensuing six months from among about a dozen who have placed their services at its disposal. In this case the 3*s.* per unmarried and 12*s.* per married man are paid in full to the practitioner thus chosen. It may be mentioned that it is the aim of the German medical organisation to obtain remuneration for services rendered to sick club patients according to the lowest charges of the tariff, and this resolution forms part of its working programme.

In considering the above conditions it must not be forgotten that dispensing is forbidden to medical men and is a monopoly of the pharmacists. On the other hand, every prescription has to be charged for according to the provisions of the Imperial Medicine Tariff, which sets forth in detail the amount to be levied for each single constituent according to the exact amount prescribed; further, certain charges for the various manipulations in compounding a prescription, and, lastly, the price of the bottles, &c., is also fixed, the total arrived at being the amount charged to the patient. In certain German States the Government requires the pharmacist to grant a rebate (10 to 15 per cent.) on all prescriptions for sick club patients. No prescription may be repeated on a sick club's account unless it bears the medical man's signature and date on each repetition.

In view of the trend of political aspirations to-day, it is interesting to note that the nationalisation of the medical and pharmaceutical service figures on the programme of the German Social Democratic party, which contends that every citizen has a right to free medical attendance at the cost of the State; and this proposal has even been discussed in some of the State Parliaments.

Methods Adopted by the Sick Clubs to Cut Down Medical Expenditure.

It is a regrettable fact, however, that the introduction of so beneficial a measure as compulsory insurance against sickness, backed by the assistance extended to the dependents upon the sick man during his incapacity for work—a high moral

factor for every wage-earner, should have been followed by serious divergences of opinion between the authorities of the organisations and the members of the medical profession. In their endeavour to afford the insured the greatest possible benefits the sick clubs have, so far as the medical man is concerned, consistently closed their consciences to the precept of "live and let live." By every possible means they strive to reduce the expenditure relating to medical attendance. In fact, they go so far as to dictate what the practitioner may and may not prescribe for members. This is effected by means of a list enumerating certain more expensive drugs, wines, mineral waters, &c., which must either be replaced by less costly preparations, or permission to prescribe them must be obtained from the club committee. Again, a collection of formulæ has been elaborated calculated to meet general cases and costing as little as possible. In liniments, for instance, olive oil is replaced by rape-seed oil; instead of vaseline or lanoline, lard is to be used as an ointment base. This mania for saving goes so far as to exclude the use of divided powders. The medical man has to prescribe the full quantity, and the directions read: "Take as much as will go on the point of a knife." In the case of potent drugs the danger of so inaccurate a method of dosage is apparent. Simple solutions of salts are also banned: 10 grammes of potassium iodide are prescribed, and the patient has to dissolve this in a wine bottle full of water. The bottles, ointment-pots, &c., have to be returned to the pharmacy, otherwise they are charged to the member himself. The above instance but a few of the restrictions imposed to obviate "unnecessary" expense to the clubs.

"Forewarned is forearmed," and the British practitioner would do well to consider the experiences of his Continental colleagues so as to be in a position to safeguard his interests on the introduction of social measures nearly affecting his material position in his own country.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The University of Bristol.

THE winter session opened on Oct. 3rd without any definite ceremony. The graduation ceremony is reserved for Oct. 20th, and the new wing is to be formally opened by Lord Winterstoke on Nov. 15th. This wing, it will be remembered, provides new quarters for the departments of chemistry and physiology. The removal of the latter from its somewhat cramped quarters in the medical building leaves space for other departments, and has made possible a very considerable extension of the students' room by destruction of the wall which separated the original room from the medicine lecture theatre and fusion of the two rooms in one. The old physiology lecture theatre will be available for medicine and surgery, and one of the old physiological laboratories is devoted to dental mechanics. It was hoped that the wing would be ready for use at the beginning of the session; but in spite of strenuous efforts on the part of the builders much remains to be done. Another important addition to the University has to be recorded. The two theological colleges, the Western College and the Baptist College, are to be regarded as an institution in association with the University, arrangements having been made for the recognition of the teaching staff as members of the teaching staff of the University. To this end an advisory committee has been formed with the Vice-Chancellor as convener. The Western College is housed in a very good new building close to the University, and the Baptist College is about to be rebuilt on a site separated only by a road from the new wing of the University. On Oct. 8th a students' reception was held in the large hall of the University, at the invitation of Sir Lambard and Lady Owen. Each faculty had a table decorated in a distinctive colour, and bows of corresponding colours were served out for students to wear. As each student also wore a piece of paper bearing his name a method of automatic and general introduction was secured.

Decrease of Vaccination in the West of England.

Vaccination in the West of England has been falling off very considerably, especially in the urban districts, and the experience of the Cirencester (Gloucestershire) board of guardians is fairly applicable to most of the unions in the West. The returns recently issued by this board show that whilst in the rural districts the number of exemptions had remained practically stationary, in the urban districts the number had now increased to such an extent that they were equivalent to one-half of the total number of births.

Poor-law Treatment of Consumptives.

At a recent meeting of the Bristol board of guardians the hospital committee reported in favour of the establishment of a sanatorium for the treatment of early and advanced cases of phthisis in men, women, and children, and spoke of a property within reach of Bristol, in the Somersetshire hills, which might be acquired for that purpose. Boards of guardians have adopted a similar course in Liverpool, Bradford, Newport, and elsewhere; and the present accommodation in Bristol is unsatisfactory. There is a great deal to be done at Southmead before it can be considered an efficient sanatorium; and the committee feels that as such changes are necessary and must be shortly undertaken it would be better policy to start an altogether new institution where the treatment would be more efficient and where consumptives would be segregated from those whom they might otherwise infect. The committee's calculations show that such a plan would be as economical in the long run as a patching scheme. The whole matter was postponed for fuller discussion and examination.

The Bristol City Infectious Hospitals.

The typhoid carrier who is being kept under observation at the Ham Green Fever Hospital has troubled the minds of certain members of the Bristol health committee, who object to the expenditure of public funds in maintaining a patient for what they consider to be the gratification of scientific curiosity. Fortunately, the medical officer of health, Dr. D. S. Davies, was able to assure them that the investigations were likely to yield results of practical value. At the same meeting it was proposed and decided to spend about £5000 in extending the accommodation for infectious disease by adding buildings to the Novers Hospital. This will bring the number of beds nearer to the Local Government Board standard, of which the present total falls short.

Control of the Tuberculous Poor.

The Plymouth board of guardians has been seeking the support of various boards of guardians in the West of England for approval of a resolution asking the Government to give authority to the guardians to detain in the workhouse infirmary all persons suffering from tubercular phthisis who are in receipt of outdoor relief. The proposal does not seem to have met with much support; the St. Thomas' (Exeter) board allowed the letter "to lie on the table," one of the members remarking that the suggestion would mean a great hardship on the poor.

The Exeter District Nursing Association.

The nurses' home in connexion with the newly-formed District Nursing Association was formally opened on Sept. 29th by the Mayor of Exeter in the presence of a large gathering, which included Mr. H. Duke, K.C., M.P., Colonel Cardew, and Dr. H. Davy. The association employs a head-nurse and two assistant nurses, who commenced their duties on Oct. 3rd. It is estimated that an annual income of about £300 will be required to carry out the working of the undertaking. The cost of furnishing, &c., will be probably £250, making a total of £550. Of this sum £420 have been obtained, leaving £130 still to be raised.

Veterinary Surgeons and Armorial Bearings.

At Barnstaple, on Oct. 6th, a local veterinary surgeon was summoned by the Devon county council for using armorial bearings without a licence. For the defence it was contended that the crest was that of the Royal College of Veterinary Surgeons and that the members of that college had a right to use the college arms on notepaper, billheads, &c., when used for only professional purposes. The bench of magistrates eventually dismissed the case and allowed the defendant costs and also the advocate's fee.

Proposed Medical Officer of Health for Cornwall.

At a meeting of the Contagious Diseases (Animals), Sanitary, Housing and Town Planning Act Committee of the Cornwall county council held at Truro on Oct. 6th, under the presidency of the Hon. John Boscawen, it was unanimously decided to recommend the county council to appoint

a medical officer of health for the county of Cornwall, at a salary of £400 per annum, rising to £500 by yearly increments of £25.

Bristol's Memorial to King Edward VII.

After long deliberation it has been determined by the Lord Mayor and his committee to erect an equestrian statue of King Edward VII. in front of the Victoria Rooms, Clifton, using the opportunity for the acquisition of ground at present surrounded by unsightly railings, and in the future to be used for some kind of open space. This is a much-needed improvement, but some disappointment is felt by those who had hoped that the King's memory would be perpetuated by means of a central hospital fund such as exists in London.

The late Mr. R. G. Worger of Radstock (Somerset).

Two stained-glass windows were dedicated in the chancel of the parish church of Radstock on Oct. 2nd, which have been erected as memorials to the late Mr. Richard George Worger, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. One window contained a representation of St. Luke, "the beloved physician," and was erected by subscriptions from the inhabitants of Radstock. The other was emblematic of a Red Cross Knight, and was given by the deceased's comrades in the 2nd South-Western Mounted Brigade Field Ambulance, R.A.M.C. (T.F.), in which Mr. Worger held the rank of surgeon-captain. Mr. Worger, of whom an obituary notice appeared in THE LANCET, died on July 10th last. He was extremely popular in Radstock, took a great interest in the social and religious life of the town, and was for several years churchwarden of the parish church.

Oct. 10th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Infantile Mortality.

WHATEVER may be thought of the use of bribery in the form of prizes for the mothers who have succeeded in rearing their children as far as the completion of their first year, there is no doubt of the philanthropic motives that have inspired Mr. Alderman Broadbent of Huddersfield in his crusade against the unnecessary loss of infant life which disgraces many parts of our country. Warrington has had a high infant death-rate, and the public conscience has been roused to do something towards its reduction. A public meeting, held under the auspices of the Warrington Guild of Help, was very successful, 2000 people being present. Alderman Broadbent was the principal speaker. Dr. Joseph, the deputy chairman of the health committee, gave the movement the sanction of the municipal council, saying that the council would welcome the assistance of the Guild of Help. A letter was read from the Bishop of Liverpool, saying that the "infantile mortality was a disgrace to our civilisation and our Christianity, and he was thankful that the question was being discussed by the citizens of Warrington in public." The town council has adopted a report of the health committee submitting a scheme by the medical officer, involving the appointment of two lady inspectors and the acceptance of voluntary assistance, probably of lady members of the "Citizens' Guild of Help." The scheme thus sketched out bears much resemblance to that which has been productive of so much good among the poorer part of the population of Manchester. Help in poverty will, as was said long ago, always be needed, but that the amazing ignorance among the poor, which is one of the chief causes of the high death-rate among infants, should exist in these days, after the long years in which compulsory education has had free play, is of itself eloquent proof of the non-practical character of the teaching which has gone by the name of education. There are some signs of improvement as to this, and perhaps we may hope that those who rule in these matters may allow common-sense a more prominent place in the scheme of education.

"Christian Science."

The striking case of what may almost be called death by "Christian Science" that took place at Urmston, and to which your medico-legal correspondent referred last week, shows how utterly irrational are these fanatics. The facts are probably fairly well known. A man, aged 53, became lame three years ago, and as he gradually became worse he saw Dr. J. Clegg at Urmston, and was advised to see Dr. A. H. Burgess, who advised him to have the leg amputated. In his evidence at the inquest the son said his father had a horror of operations, and was also a Christian Scientist. Dr. Clegg was dismissed, and a Mr. Pitfield, a Christian Scientist practitioner, was called in. Dr. Clegg said that if the leg had been amputated a good recovery might have been looked forward to. Mr. Pitfield, whose only occupation seems to be that of a Christian Science practitioner, said the patient asked him if he would help him with Christian Science, so he prayed with him, read the Scriptures and the Christian Science text-book, "Science and Health," but no treatment was given to the leg. In answer to the coroner as to the failure of his treatment he answered, "I cannot say it was a failure." The coroner did not agree with this, and the jury seemed to wish to return a verdict of manslaughter, but the coroner told them the only verdict they could give was "Death from septic poisoning," and as Mr. Statham had acted on his own responsibility they could not add a rider. The coroner made some strong remarks on the conduct of Mr. Pitfield. A letter has appeared in the *Manchester City News* which illustrates the strange character of what presumably stands for reasoning. He objects to an article in a local paper headed a "Christian Science Victim," and says it is not easy to see why it should not be a "Medical Science Victim." "To be sure, he was offered the chance of an operation, a mere chance of life, as the doctor very fairly admitted. ..... But surgery is not healing, and a grave operation with a chance of success cannot be the true scientific healing," and so on. One Sunday night at a Roman Catholic church in Manchester Father Day delivered a trenchant and scathing attack on the principles of the so-called Christian Science, saying that the text-books read like the ravings of a madman. It seems as if this delusion were spreading, and it might be well for the clergy of all denominations to warn their flocks against the absurd doctrines of Christian Science.

The Salford Guardians and Hope Hospital.

It may be remembered that some time ago the Salford guardians were unfortunate enough to come under the ban of the medical profession as regards an appointment at the Hope Hospital, which is under their control. They are now at cross purposes with the Local Government Board as to the appointment of a medical officer to the hospital. To their surprise, their choice of a local practitioner for the appointment of medical officer was not accepted by the Local Government Board, which intimated, in a letter read at the meeting of the guardians held on Oct. 7th, that it still "did not feel able to assent to the appointment proposed by the guardians." The feathers of the guardians were naturally ruffled somewhat, but a lady guardian moved that they should advertise the position again, and said that if the decision of the Local Government Board had been accepted at first it would have saved the guardians from an embarrassing position. This was seconded by another lady. The chairman of the Hope Hospital committee proposed an amendment which was somewhat militant, "declaring the proposed appointment the best that could be made in the interests of the poor in that institution," and he protested against "the usurpation of the rights of the guardians by any London authority." A valiant stroke for self-government. This was backed up by the chairman, who said "it was a battle between public representatives and the red tape of central officialdom." One reverend gentleman thought the central authority should be respected. However, the amendment was carried against the sweet reasonableness of the ladies, and the guardians remain at "loggerheads," as it is called in Salford, with the Local Government Board as to this very important appointment. At present the duties are carried out by a locum-tenent at a stipend of 6 guineas a week.

"Spotted Fever" in Cheshire.

It was reported from Macclesfield yesterday that a case of spotted fever had occurred there in a boy 11 years old. It is said that he had been in the Macclesfield Infirmary for some days under treatment for meningitis, when it was suspected that he was suffering from spotted fever. On

Friday last a sample of fluid was sent to the Lister Institute, and on Saturday the boy was removed to the isolation hospital, and yesterday the medical officer, Mr. J. H. Marsh, received a provisional diagnosis of spotted fever. It is not known how the boy came by the disease.

Oct. 11th

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Medical Session.

THE classes in the Faculty of Medicine of the University of Leeds were resumed on Oct. 4th, when Professor F. Howard Marsh, the Master of Downing College, Cambridge, and professor of surgery in that university, distributed the prizes and delivered an introductory address (see p. 1119). There was a good attendance of the staff, of the students, and of the general public, and the proceedings were presided over by the Vice-Chancellor. The main part of the address dealt with the vexed and largely discussed question of the curriculum and the amount of time that could be devoted, under the existing arrangements, to actual clinical work. The University of Leeds has recently made certain alterations in the curriculum which have secured, at the expense of some concentration of the time devoted to the earlier subjects but without it is hoped sacrificing their interests, an increase in the length of time devoted to the more purely professional subjects. And as in these the number of systematic lectures has been diminished the time of the students which can be devoted to clinical work will be increased. Professor Marsh's remarks on this score therefore may be regarded as confirming the wisdom of the alterations referred to. A very interesting part of the address was that in which he gave some details of the life and work of William Hey, the founder of the school, whom he deemed worthy to be mentioned along with Cooper, Hunter, and Lister. Following the custom of many years, the annual dinner of the medical profession of Leeds and district was held at the Queen's Hotel on the same day that the session was opened, when Professor Marsh was the chief guest, the chair being taken by Professor R. Lawford Knaggs.

Lyddon Hall: Students' Residential Chambers.

Owing to the death of Mr. G. Herbert Rowe a vacancy has arisen in the wardenship of this residential hall. Professor Jamieson, who has lately been appointed to the chair of Anatomy, has been approached in the matter and has consented to undertake the duties. Lyddon Hall is pleasantly situated within convenient distance of the medical school and the other University buildings, and was at one time the residence of Sir Clifford Allbutt. Professor and Mrs. Jamieson are very cordially wished every success in their undertaking.

Alarming Fire at the General Infirmary.

On the morning of Oct. 7th there was a serious outbreak of fire at the General Infirmary, which was happily confined to the upper wards of one block and was unattended by loss of life or disaster of any kind. The block affected was the most recently built of those occupied by patients, and was opened 18 years ago. It is composed of three storeys with front and back wards in each, connected with one another by a local administrative portion in which there are some small wards with access from a main staircase and occupying mezzanine floors. The three storeys are connected with the rest of the building, on the ground floor by a covered way, on the first floor by a gangway, with the main corridors of the infirmary, and on the top storey by a bridge with the terrace. It is noteworthy that this last connexion was made only a few years ago on the suggestion of the late Mr. W. H. Brown. On this occasion it is true that its non-existence would not have determined a catastrophe, but its presence greatly facilitated the removal of the children who occupied the top storey. The fire was first detected by a passer-by, and on the prompt arrival of the firemen its site was found to be in the false roof. The nurses who were on duty got the first alarm from the firemen, and at once set about removing all the patients. Promptly other nurses, porters, servants, and members of the resident staff were at work, and in a few minutes, without panic or hurry, all the patients were removed to various places of safety, and practically all the furniture of the wards was removed. Though, as the chairman of the board said in his official statement, the complete safety of the inmates was never for a moment in doubt, the rapid removal of some 90 patients was a creditable performance, and it left a clear field for the fire brigade to fight the matter out. The roof of the building was burnt and in great part fell in, but the fire was confined to the top storey, and was got under in about two hours. Kindly offers of assistance were at once forthcoming from several of the neighbouring institutions, but it was not found necessary to accept these. The date of discharge of a good many of the patients in the semi-convalescent hospitals was anticipated, and some of the patients found accommodation there. One of the large wards had just been completely overhauled and was to have been occupied in a week; this was at once got ready and provided space for 28 patients. Some others found accommodation in various parts of the building, and with the exception of the closing of the out-patient department on the afternoon of the fire there was no interruption to the work of the infirmary.

Oct. 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary: The Nurses' Prize-giving.

AT the nurses' prize-giving in the Edinburgh Royal Infirmary on Oct. 7th the prizes were distributed by Lord Ampthill. Lord Provost Brown presided over the gathering, which was held in the nurses' recreation-room in the infirmary. Lord Ampthill, after the presentation of the prizes, addressed the nurses, speaking in terms of high appreciation regarding the work done by the nursing profession. He went on to urge the advantages of a system of registration for nurses, maintaining that for the sake of both the public and the large body of fully trained nurses the sanction and the protection of the law through the method of registration were necessary. Mrs. George Kerr, one of the managers of the infirmary, referred to the resignation of Miss Bell on her appointment as matron in Melbourne, and expressed regret that the infirmary was to lose her services. Mr. Walter B. Blaikie, in moving a vote of thanks to Lord Ampthill, referred to various recent improvements in the conditions under which the nurses worked. A new nurses' home had been added to the institution, the dining-room accommodation had been increased, and an improved pension scheme had been instituted.

Dundee Medical Appointments.

Dr. John Logie, a graduate of the University of Edinburgh, has been appointed resident medical assistant to the Dundee Royal Infirmary. Dr. Logie took honours in most of his classes. The Dundee school board on Oct. 4th appointed Dr. A. B. MacArthur Thomson, Barking, Essex, as assistant medical officer at a salary of £250. Dr. Thomson graduated at the University of Edinburgh eight years ago. He obtained the D.P.H. of London this year.

Hostel for Senior Medical Students at Glasgow.

A residency or hostel is to be opened near the University and Western Infirmary on Monday, Oct. 17th. The hostel is at 9, University-avenue, and is in telephonic communication with the Western Infirmary, so that the students can be communicated with and get the advantage of seeing urgent medical and surgical cases, and in this way add to their practical experience. The charge for residence in the hostel will be £1 1s. per week.

Aberdeen City Poorhouse Medical Officership.

The time for receiving applications for the medical officership at the Aberdeen city poorhouse has expired, but no application for the post has been received. The matter will now come before a meeting of the Aberdeen parish council on Oct. 11th. It will be remembered that when first the post was advertised the salary offered was only £75. The local medical men contended that this was not a fair salary and that at least £150 should be given. The council then offered £105, but, as stated above, no application has been received.

The University of Aberdeen: Changes in the Staff.

The following changes have occurred in the Aberdeen University medical staff: Experimental Physiology: John

Elrick Kesson, M.B., to be lecturer. Forensic Medicine: David Rennet, M.D., D.P.H., to be lecturer. Anatomy: Norman James Calder, M.A., M.B., to be assistant. Materia Medica: Walter James Dilling, M.B., to be assistant. Pathology (Special): James Watt, M.A., M.B., to be assistant. Surgery: G. H. Colt, F.R.C.S., to be assistant.

Aberdeen Branch of the Red Cross Society.

A meeting was held of the Aberdeen Branch of the Red Cross Society on Oct. 4th, following the large one of the previous week. Lady Aberdeen again presided, and a leaflet prepared by her, explaining the methods to be followed in the organisation of the County of Aberdeen Branch and in the formation of classes throughout the county, was carefully gone into. Lady Aberdeen undertook to have copies of the leaflet circulated through the county, and it is hoped that it will be the means of creating interest in the movement. A form of standing orders was also gone over and approved, and the appointments made at the last meeting were confirmed. The movement will be now advanced by the vice-presidents, under the direction of the divisional presidents, having classes and voluntary aid detachments formed in their district. The fee for membership is £1 1*s.*, and for associateship 5*s.*

Gift of Portraits of Emeritus Regius Professor A. Ogston, University of Aberdeen.

At a meeting of the Aberdeen University Court on Oct. 4th, Professor George Adam Smith presiding, a letter from Dr. J. Mackenzie Booth was read, asking on behalf of the committee the court's acceptance of the portrait of Emeritus Professor Ogston to the University of Aberdeen. The portrait to be presented to Professor Ogston himself will be presented at the same time and place—namely, the afternoon of Oct. 14th in the Portrait Gallery of Marischal College, the court having signified its pride and great pleasure in accepting the portrait to be presented to the University. On the occasion Professor Matthew Hay will accept the portrait for the University, owing to the unavoidable absence of the principal. These portraits have been subscribed for by medical graduates throughout the world, and painted by Mr. Fiddes Watt, A.R.S.A.

Oct. 11th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Dublin.

Sir Charles Cameron, medical officer of health of Dublin, has issued his annual report on the health of the city and on the sanitary work performed in 1909. The delay in its appearance is due to a cause that everyone regrets—the recent severe illness of its author. He urges on the corporation the necessity of new enactments which would tend to bring the standard of public health as nearly as possible up to that of English cities. It may reasonably be asked why the corporation does not make full use of the powers it has before asking for more? The dirty condition, even of the principal streets of Dublin, is proverbial.

Health of Waterford.

The public health of the city of Waterford has been for some time so unsatisfactory that the Local Government Board has at length ordered an inquiry into the sanitary conditions of the city to be held by two of the inspectors of the Board. In the letter to the corporation announcing this intention the Local Government Board points out that the death-rate from all causes in the past three years has amounted respectively to 21·7, 21·3, and 19·1 per 1000, while the death-rate from the principal epidemic diseases has for the same period reached the high figures of 2·2, 3·1, and 2·4 per 1000—a record unapproached by any of the important town districts in Ireland. The corporation is very indignant at the inquiry being held.

Presentation to Sir George O'Farrell.

Last week the members of the Irish Lunacy Service presented an address to Sir George Plunkett O'Farrell, who has recently retired from the position of Inspector of Lunatics. The address is to be followed by a portrait. The esteem in which Sir George O'Farrell is held was shown by the fact that nearly all the medical superintendents of Irish asylums attended in Dublin to take part in the presentation.

Sudden Death of Mr. P. J. Fagan.

It was with much surprise and sorrow that his professional friends heard of the death of Mr. P. J. Fagan, surgeon to St. Vincent's Hospital. Mr. Fagan complained of pain in his chest on Sunday night last, but on Monday he went about his usual work. On Monday evening, however, he was seized with angina pectoris and died in a few moments. Besides being surgeon to St. Vincent's Hospital, Mr. Fagan was for many years an active member of the staff of the Catholic University School of Medicine in the departments of physics and anatomy, and since the establishment of University College he has been chief demonstrator of anatomy. He was only 46 years of age, and he leaves a widow and three young children.

Charles Magill, M.D. R.U.I.

It is with sincere regret I announce the death of one of the best-known Ulster practitioners at his residence, Lisburn, which occurred on Oct. 5th, suddenly, from Bright's disease, which assumed a very serious condition on Oct. 4th, when uræmic convulsions set in, followed by heart failure. Dr. Magill belonged to Dundrod, county Antrim, being the son of a well-known clergyman, the Rev. W. Magill, whose congregation was in that district. After a successful career at Queen's College, Belfast, he graduated M.D. and M.Ch. of the Royal University in 1879, and became L.M. R.C.P. Irel. in the same year. For a short time he was house surgeon in the Belfast union hospital; he afterwards practised for a time in Crumlin, but in 1882 he removed to Lisburn, where he rapidly built up a good practice. He was medical officer of the local district of the Great Northern Railway and the Ulster Provincial (Friends') School. A man of an extremely genial disposition, he was much esteemed by his patients as well as by the general public. He leaves a wife and two children—a boy and girl—for whom sincere sympathy is felt. Dr. Magill, who was 52 years of age, was buried in Lisburn.

What Ailed the Pig?

At the Portadown petty sessions on Oct. 10th a farmer was summoned for exposing for sale in the Portadown pork market the carcass of a diseased pig which was alleged to be unwholesome and unfit for food. Mr. J. L. Rowlett, medical officer of health, and Mr. R. W. Thompson, veterinary surgeon, said that the pig was suffering from tuberculosis, and that in their opinion the carcass was not fit for human food. Dr. R. J. Rowlette, lecturer in pathology at Queen's College, Galway, and pathologist to the Steevens and Rotunda hospitals, said that he found tubercle bacilli in the glands of the animal and that the portions of the carcass submitted to him were infected with tuberculous disease. For the defence, Mr. J. McAleer, veterinary surgeon, stated that he examined the pig and formed the opinion that it was fit for the food of man, and he would not have condemned it. Dr. F. McDonald said that the pig was not suffering from tuberculous disease. It was a sound, healthy pig, fit for the food of man, and it was not suffering from any disease. Professor E. J. McWeeney said that he could not find any traces of tuberculous disease in the portions of the carcass submitted to him. He found no tubercle bacilli in the tissues. He was distinctly against all kinds of alarmist rumours that would result in good carcasses of meat being condemned because a small portion of the carcass might bear evidence of disease. He was then asked to explain the following passage from the report of the Royal Commission on Tuberculosis: "In view of the greater tendency of generalisation of tuberculosis in the pig, we consider that the presence of tubercular deposits in any degree should involve seizure of the whole carcass and organs," and in reply Professor McWeeney said that was not exactly infallible, and men who had interested themselves in this question were entitled to their own opinions. He quite accepted Dr. Rowlette's statement that he found tubercle bacilli in the specimen sent him, but he (Professor McWeeney) failed to find them in what he examined. The case was dismissed, but the town council of Portadown, it is said, will appeal.

(FROM OUR OWN CORRESPONDENT.)

Organic Compounds of Antimony and Arsenic in the Treatment of Trypanosomiasis.

AT a meeting of the Academy of Sciences held on Sept. 26th M. Laveran made a communication on the treatment of trypanosomiasis with organic compounds of antimony and arsenic. He said that M. Yvon, after preparing a mixture of the emetic compound of antimony and aniline with the emetic compound of arsenic and aniline, had by crystallisation obtained from it fine hexahedral crystals of a pale violet colour containing both antimony and arsenic. M. Laveran had made trials of this substance on guinea-pigs infected with Trypanosoma evansi, Trypanosoma gambiense, Trypanosoma dimorphon, and Trypanosoma congolense. It was employed in a watery solution of 2 per cent. strength, which was injected into the muscles of the thigh in the following quantities: For guinea-pigs of 500 grammes, a dose of 0·01 gramme; for guinea-pigs of 600 grammes, a dose of 0·0125 gramme; and for guinea-pigs of 700 grammes, a dose of 0·015 gramme. The treatment was not commenced until the trypanosomata were fairly abundant in the blood of the animals; five injections were given at intervals of four or five days; as a rule they did not produce any ill-effects, but in some instances there was severe inflammation without suppuration. Recovery was considered to have taken place when the blood of the animals remained free from trypanosomata for three months, and this condition was fulfilled by 15 of the guinea-pigs which had been infected with the four species of trypanosoma already mentioned. In 11 of these animals recovery took place after a single course of treatment consisting of five injections; in 4 cases there was a relapse, followed by recovery after a second course of treatment. It was not yet possible to say whether the new preparation would be serviceable in sleeping sickness. There was some reason to fear that injections of it into the muscles of the human subject would prove too irritating, and that intravenous injections might be necessary, which would be a serious objection. It has, however, been found that an injection of it into the muscles of a monkey's thigh did not cause any inflammatory reaction and did not seem to be painful.

Conference on Cancer.

As already mentioned in this column, the International Conference on Cancer met in Paris on Oct. 1st. The inaugural addresses and other preliminary business occupied the forenoon of that day, and in the afternoon there was a discussion on the histology and histological diagnosis of cancer. Professor Czerny of Heidelberg was in the chair. Professor von Hansemann, speaking in German, proposed the appointment of a commission composed of all the foreign delegates for the purpose of drawing up an international nomenclature for use in connexion with cancer, this nomenclature to be submitted to the conference which would be held in three years' time. Professor Delbet drew attention to the inconveniences resulting from the fact that in different countries identical lesions received dissimilar names and the same words were often used in different senses. M. Pierre Nadal said that in the present state of our knowledge it was impossible to make a complete classification of cancers. M. Poziawecki expressed the opinion that the word cancer should be discarded and that its place should be taken by the adjective cancerous, which would be applied to the malignant forms of various tumours. Professor P. Marie spoke in favour of the proposal made by Professor von Hansemann, as well as on the utility of preserving documents for future use; he said that Professor Delbet had, in conjunction with M. Ménétrier and M. Herrenschmidt, compiled a nomenclature which, although it might not be complete, was a useful contribution to pathological terminology. The second subject on the official programme was the histogenesis of cancer. It was introduced by M. Brault and M. Faroy, who said that cancer when considered with reference to its histogenesis appeared to be a deviation from the laws of normal development, and from the principles which governed the maintenance, the renewal, and the repair of the tissues, but it was impossible to say exactly what was the active agent in this metamorphosis. M. Ledoux-Lebard introduced the subject of statistics. He recommended the adoption of uniform and comparable methods, the use of inquiry sheets presenting similar features but with some variations, and the formation of an international commission on the statistics of cancer. Dr. Carl Otto of Copenhagen, in discussing the duration of cancerous diseases of the digestive organs, gave some particulars of 196 cases which had been followed from the commencement of the disease until death, all of them having been examined post mortem. He said that the commencement of the disease and the appearance of the first symptom were in general not simultaneous but the latent stage was disregarded. On Oct. 3rd the meeting took place in the amphitheatre of Professor Delbet in the Hôpital Necker. Professor Kortewez and Professor Delbet spoke on the subject of the surgical treatment of cancer and M. Rovsing on the general treatment of cancer. Professor Marie and M. Clunet discussed the action of the X rays on malignant tumours. Professor Segond presented a report on fulguration in the treatment of cancer, his conclusions being generally unfavourable. M. Vidal of Algiers described various forms of serum treatment which have been proposed for malignant tumours. M. Récamier of Paris dealt with the subject of assistance for cancerous patients. In the subsequent meetings Dr. Weinberg delivered an address on the hæmodiagnosis of cancer, and Professor Winter, speaking on the subjects of post-graduate medical instruction and the education of the public, said that increased knowledge would in the course of time enable operations for cancer to be performed in an early stage of the disease.

Cholera in Marseilles.

A party of emigrants coming from the Piræus in the *Bosphore* recently arrived in Marseilles, where they stayed at a hotel, and two days afterwards several of them fell ill. Three who presented all the symptoms of cholera were isolated, and two of these patients have died. The remainder of the party was then removed to the lazaret at Frioul.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Death of Professor Chrobak.

Professor Chrobak, the well-known professor of obstetrics and gynæcology in the University of Vienna, died a few days ago after a prolonged illness. This famous surgeon was really a self-made man who by his great abilities and knowledge obtained the position of the most esteemed and influential director of the clinic in the general hospital. He was born in 1840, and on graduating as M.D. took up the study of diseases of women, in which subject there was at that time hardly any teaching. He soon became *privat-docent* in his specialty, and was appointed professor in 1880. His principal published works are the "Text-book on Diseases of Women"; the gynæcological part of Stricker's "Text-book of Histology"; and the section on "Gynæcology" in Nothnagel's treatise. He did much towards the introduction of gynæcological wards in the smaller hospitals, and the present system of instruction of students in diseases of women is chiefly due to his endeavours, as is also the teaching of midwives. His final exertions were devoted to the construction of the new gynæcological clinics which he knew he would not take over as illness had incapacitated him for active work; the modern up-to-date design of these buildings is chiefly due to his ideas. In 1908 he resigned his post in favour, as he said, of his favourite pupil, Professor von Rosthorn, who died so suddenly only a few months ago. Another of his early pupils is Professor Wertheim, who succeeded Professor von Rosthorn and is well known as the originator of a radical method of operation for cancer of the uterus. Professor Chrobak's kind and thoughtful way of dealing with patients was known everywhere, and his motto, *Primum non nocere*, was not only impressed upon all his pupils, but was visible in every operating theatre and ward of his clinic.

International Congress on Physiology.

The Eighth International Congress of Physiology took place in Vienna from Sept. 27th to Oct. 1st. The president

of the Congress was Professor Exner, and the Government, as well as the municipality of this city, gave a hearty reception to the Congress. After the usual preliminary addresses of welcome delivered by the President and the representatives of the State, the city, and scientific corporations, Professor Richet, speaking in French, delivered the introductory discourse, taking for his subject "Humoral Teaching in Physiology." He explained how the old theory of the "humours" of the animal body had regained its importance by the researches of modern physiology, which showed how the presence of "humours" of special substances in the liquid form were responsible for many conditions of life or death. The meetings took place partly in the University and partly in the physiological laboratory of the Institute for Anatomy and Physiology. Numerous papers were read, some of the more important among them being as follows. Professor Tshikawa of Japan read a paper on the Changes in the Protoplasm of Amœba under the Influence of Narcotics and Asphyxia. He showed that the protoplasm differentiated itself into two parts, a change which, however, did not occur if the toxic substance was removed. A paper which excited much interest on account of the recent development of flying machines was read by von Wendt of Helsingfors on Metabolism at High Altitudes. He found that nitrogen was retained in the tissues and that medium altitudes increased the formation of hæmoglobin and red corpuscles, whilst the higher altitudes increased the muscular development in a greater degree. Professor Hensen of Kiel read a paper on the Methods of Examination of Plankton, the "blood of the ocean," for which purpose he has constructed various ingenious forms of apparatus. The old problem of diabetes was taken up by Dr. Boruttau of Berlin, who has found that the heart of mammals contained glycogen, and that a change of diet caused also a change of the percentage of glycogen. He said that diabetic patients had lost in variable degrees the ability to utilise all ingested carbohydrates and albumin. Dr. Reach's experiments showed that after removing nearly all the pancreas ingestion of raw meat caused sugar to appear in the urine in dogs. Professor Kreidl of Vienna and Professor Kinoshita of Japan have studied the phenomena of the electric discharges which occurred in the Torpedo marmorata when it was placed in water free from salt. Under this condition rapid discharges occurred, until the electric organ was exhausted, which required about 30 minutes. The animals regained their electric potency quickly when returned to the sea, and could be "discharged" several times without harm. Cocaine and chloral-hydrate, even in very small doses, immediately stopped the electric discharge in water free from salt, whilst the administration of strychnine caused electric discharges even in sea-water. Professor W. M. Bayliss of London gave details of his experiments on the osmotic pressure of colloids. Professor Stirling also selected a theme of general physiological interest, whilst the problems connected with thermopenetration were discussed by Dr. Ullmann and Dr. Berndt. Quite a special part of the proceedings was devoted to the electro-cardiogram, and the correctness was shown of the opinion of Zbyszewski that the electro-cardiogram was an indicator of the currents in the cardiac muscles, the preponderence of the left ventricle in this respect being clearly manifested. Dr. Prizbram demonstrated the method adopted by him to ensure a constant or variable climate for his biological experiments at temperatures advancing by successive differences of 5° C. up to 40°; at the same time the animal could be placed under varying conditions of humidity, colour, and light. Dr. Kammerer showed animals which had inherited differences of colour and other bodily qualities from the parents under modified conditions of life. The exact measurement of the resistance of air in the nasal passages was demonstrated by Professor Gärtner. One of the most notable papers was a commemoration by Dr. von Ebner of the centenary of Schwann. The fundamental discovery by that eminent physiologist of the cellular structure of the living animal organism has been the basis on which modern scientific research in medicine has been made possible. With regard to the sight-seeing part of the programme, mention must be made of two events—namely, a visit to the Vienna Biological Experimental Institute, where much work of a most interesting nature is being done in a quiet way, and the unveiling of a statue of Gregor Mendel, the famous priest, who discovered the laws named after him, the Mendelian laws of heredity. He was a native of Brünn, in Austria, where a monument to him has been erected by a number of his followers, and an official deputation from the Congress was present at the unveiling ceremony.

Oct. 10th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending Sept. 3rd show 1770 deaths for all India as compared with 1325 in the week preceding. The provincial figures are: Bombay Presidency, 857 deaths; the Central Provinces, 248; the United Provinces, 104; Bengal, 85; and Madras, 73. Hyderabad State returns 141 deaths; Mysore State, 90; and Rajputana and Ajmer Merwara, 133.

Beri-beri in India.

A report by Major A. Hooton, I.M.S., on the first biennial meeting of the Far Eastern Association of Tropical Medicine at Manila has recently been published. The portion of it of most interest to India relates to beri-beri. The discussion on this disease centred on an admirable paper by Dr. H. Fraser and Dr. A. T. Stanton of the Institute for Medical Research of the Federated Malay States, and a communication from Dr. H. C. Highet, the chief medical officer of Siam, which in essentials tended to support the conclusion arrived at in that paper. Following up the suggestion of Dr. J. Braddon that beri-beri is connected with the consumption of over-milled or white, as contrasted with under-milled, rice, a series of experiments was carried out at the institute on fowls, the result of which, stated briefly, was that a large proportion of those fed on over-milled rice alone developed polyneuritis, while all those fed on partially husked *padi*, or under-milled rice, containing a certain amount of the polishing removed in the cleaning process, remained healthy. Practical measures were taken in various outbreaks of beri-beri by both Dr. Fraser and Dr. Highet on the lines suggested by these experiments, and previously by Dr. Braddon, with the best results, and they quoted a large number of cases in which the disease had disappeared almost immediately on the substitution of a less completely polished for a white rice diet. The conclusions arrived at by Dr. Fraser were that beri-beri is a disorder of nutrition and usually associated with a diet in which white rice is the principal constituent, and that the disease, as it appears in the Federated Malay States, can be prevented by substituting for white rice a rice which has been less perfectly polished, or by the addition to a white rice diet of the polishing which has been removed from it, or other articles rich in those substances which have been shown by analysis to be lacking in white rice. The evidence brought forward appears convincing. It was accepted also by the great majority of the members present, and, in fact, the conclusion seems to be justified that whatever the ultimate cause of the disease may prove to be, its prevention, under by far the most common conditions, has now passed beyond the stage of theory.

Native Regimental Hospitals.

A committee, comprising Surgeon-General C. P. Lukis, Director-General of the Indian Medical Service, as president, Lieutenant-Colonel W. A. Morris, R.A.M.C., Lieutenant-Colonel C. M. Moore, I.M.S., and Major Jay Gould, I.M.S., as members, with Major Bruce Seton, I.M.S., as secretary, is at present sitting in Simla to consider the possible conversion of the present regimental hospital system of the Indian Medical Service into a station hospital system, somewhat on the lines of that existing in the case of the British army.

Infant Mortality amongst Natives in the United Provinces.

As a result of the question raised at the Naini Tal Sanitary Conference with regard to the possibility of diminishing infant mortality, special inquiries have lately been set on foot in the United Provinces with a view to establishing the undoubted results to definite causes. About a year ago a systematic investigation was begun at Cawnpore at Government expense into the reasons of extensive mortality among infants under one year of age, and for a period of six months, running into the beginning of the present year, a

lady doctor and two trained *dhais* were appointed to assist in the work. The inquiry has up to the present shown that infant mortality in the United Provinces, as elsewhere in India, is largely due to tetanus or other septic disease already appreciable at childbirth. Tetanus is the most prolific source of infant mortality amongst natives in India, and its prevalence is in very large measure traced to the prejudices of untrained attendants engaged in obstetric work, whose crude and unhygienic methods of treatment afford every opportunity to the tetanus germ. It is found that through this agency infection by the specific bacillus of tetanus is brought about with appalling frequency. In nearly every case this infection proves fatal, and it has now been established to satisfaction that the so-called convulsions which carry off so many infants within a few days of birth are purely manifestations of the disease in question.

Sept. 10th.

Obituary.

CECIL HUNTINGTON LEAF, M.B., B.C. CANTAB., F.R.C.S. ENG.,

SURGEON, CANCER HOSPITAL, BROMPTON; SURGEON, GORDON HOSPITAL FOR DISEASES OF THE RECTUM.

WE regret to announce the death of Mr. Cecil Leaf, which occurred at Eastbourne on Oct. 5th at the early age of 46 and which removes from among us one of the ablest among our younger surgeons and one who perhaps hardly received the recognition due to his attainments.

Cecil Leaf was the son of the late Mr. Frederick Leaf, a member of the well-known commercial firm of Messrs. Leaf and Co., and was born in 1864. He received his early education at Marlborough and Trinity College, Cambridge, at both of which places he excelled at cricket and racquets. On leaving college he became a student at the London Hospital, and in 1890 obtained the double qualification of the English Conjoint Board, graduating also in medicine at his University. At the London Hospital he held all the house appointments, being house surgeon, house physician, ophthalmic assistant, as well as demonstrator of anatomy in the medical school. In 1895 he proceeded to the Fellowship of the Royal College of Surgeons of England, and it was confidently expected by many of his friends that his industry and talent would secure him a place upon the surgical staff of the London Hospital, to which he was deeply attached. He was not, however, so fortunate as to obtain the appointment, and his failure, which he accepted in very good spirit, led to his taking up the work of a special rather than a general surgeon. He became surgeon to the Gordon Hospital for Fistula, where he had already done some clinical work, and to the Cancer Hospital, where his sound anatomical work at the London Hospital stood him in good stead in the line of research that he adopted. This line he soon made clear to his colleagues, for in 1898 he published a work on the "Surgical Anatomy of the Lymphatic Glands," which aimed at giving by a series of well-executed diagrams the position of the chief groups of these structures. With few exceptions, all the diagrams were original, and the book filled a real gap in systematic instruction. The average student when dissecting ignores utterly all lymphatic glands and lymphatics, and examining bodies have largely refrained in anatomy tests from asking questions on the positions of lymphatic glands and vessels, possibly out of sympathy with the certain ignorance of the candidates. But when the student commences his clinical work he finds the lymphatic system of great importance, and, as we said in our review, Leaf's small book supplies just the information that he wants.

Much of his later literary performance was a development of his earliest work. He translated and edited "The Lymphatics," a section of the monumental French *Anatomie Humaine* written in the original by Dr. Gabriel Delamare, Professor P. Poirier, and Professor B. Cunéo, discharging the task with great accuracy. In the same year, that is, in 1904, he published a small book entitled "The Clinical Causes of Cancer of the Breast and its Prevention, with Analyses of 100 Cases," in which he took a wide view of malignant conditions generally, being unwilling to attribute cancer in all parts of the body necessarily to the same cause. He suggested as of principal etiological importance in cancer of the breast errors of lactation, injury, anxiety, and a tuberculous history, coming to the general conclusion that cancer of the breast is almost invariably due to a combination of causes. He made numerous contributions to the literature of malignant disease and disease of the rectum to our columns and those of our contemporaries, among which may be mentioned an article in THE LANCET on the relation of blood-vessels to lymphatic vessels in which the interesting observations added to our knowledge of the connexion between the lymphatic and blood vascular systems. Cases of such connexion have been recorded by Stenson, Meckel, and others, the veins into which the lymphatics directly opened being the venæ cavæ, the portal, renal, axillary, internal iliac, and the azygos veins. Leaf gave further examples of this connexion and showed that a direct communication existed between the small arteries in the thorax and the lymphatic vessels in that region, although the connexion is not so free as between the lymphatics and the veins.

Always methodical and hard-working, he made full use, as will be seen by this brief record, of his opportunities, and we hope that a book on cancer of the breast, which was nearly completed when his last illness laid him aside, will be published by the kind offices of his many friends. Retiring and modest, "John" Leaf, as he was affectionately called by his contemporaries, was transparently honest, upright, and the pattern of a really good man, and his death will come as a shock to his numerous friends, for he was at work as recently as August last. It was due to lymphadenoma for which he had been operated upon in June, 1909. After this he thought himself well until this summer, when a recurrence occurred and the disease progressed extremely rapidly. He leaves a widow and one daughter. The funeral took place last Saturday at Barnes.

WALTER DUNCAN THOMAS, M.B. LOND., M.R.C.S. ENG., L.S.A.

WE regret to learn the sudden death of Dr. Walter Duncan Thomas of Bundaberg, Queensland, and formerly of Llanelly, South Wales. Apparently in his usual health on August 23rd at 11 P.M., he was found by his wife sitting in his chair, dead, at 7 A.M. on the 24th. He was in his fifty-fourth year.

Dr. Thomas was well known as a young man at Llanelly, his native place, where his father, and subsequently his eldest brother, carried on for 50 years the leading practice. Educated at Epsom College, where he became a prefect and was awarded by his schoolfellows the Hodgkin and Wakley prize, he matriculated at the London University, and subsequently became a medical student at St. Bartholomew's Hospital, London. There he took the M.R.C.S. Eng. in 1879 and in 1881 the degree of M.B. at the London University. When a boy at school he had a very severe attack of acute rheumatism which affected his heart. The knowledge of this influenced him in deciding to settle in a warm climate. After making several voyages as surgeon to the Peninsular and Oriental Steam Navigation Company Dr. Thomas started practice in partnership with Dr. May, an old Bartholomew's man, at Bundaberg in 1884. He was very successful in practice and was greatly beloved by all who knew him. In 1885 he married a daughter of the late Mr. Robert Little of Brisbane, one of the leading solicitors of Queensland. Two of his three sons survive him.

The Bundaberg *Daily News*, writing of Dr. Thomas, says: "Possessed of a nature essentially retiring, yet so generously stamped with those virtues which make for true nobility, the kindliest of feeling entwined itself around his fine personality. The last of men to seek for popularity, his nature was none the less so essentially honourable, so emphatically generous, so uniformly courteous and considerate for all around and about him, that a sense of high personal esteem and deep regard represented the only human channel of thought that could adequately convey the sentiment of his friends and acquaintances towards him. The soul of honour himself, he knew no other standard of measurement for those with whom in friendly, social, or professional life he came in contact. Small wonder, therefore, that the news of the death of a citizen so widely and so genuinely esteemed should come as a shock to the community, and the news was rendered additionally distressing because of the suddenness with which it was flashed upon the people."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Rudolf Chrobak, who was until about

three years ago professor of midwifery and gynæcology and director of the "Second" Obstetric Clinic in the University of Vienna.—Dr. R. Amory, formerly lecturer in physiology in Harvard University.—Dr. Robert A. Jamieson, formerly professor of materia medica in the Detroit College of Medicine.—Dr. André Obrzut, professor of pathological anatomy in the University of Lemberg.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF ENGLAND.—At the Second Professional Examination in Anatomy and Physiology, held on Sept. 29th and 30th, and Oct. 3rd and 4th, 85 candidates presented themselves, of whom 56 per cent. were approved (including one lady—Miss Maysie Alice Marianne Collie, Otago University) and 44 per cent. were rejected. The following are the names of the successful candidates:—

Stephen Grange Askey, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Charles Sydney Atkin, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Claude Hamilton Blair Avarne, London Hospital; Stanley Samuel Beare, Middlesex Hospital; Frank Percy Bennett, St. Mary's Hospital; Edward Albert Brock, St. Bartholomew's Hospital; Percy Patrick Butler, University College; Andrew John Chillingworth, Middlesex and St. Bartholomew's Hospitals; William King Churchouse, Charing Cross Hospital; Frank Collar, Guy's Hospital; Maysie Alice Marianne Collie, Otago University; Sidney Barron Depree, St. Mary's Hospital; Hubert Roy Dive, St. Bartholomew's Hospital; George Cranston Fairchild, B.A. Cantab., Cambridge University; John Reginald Keith Fenning, London Hospital; Arthur Griffith-Williams, Cambridge University and London Hospital; Haji Sulaiman Gulamhussein Haji, L.M.S. Bombay, Grant Medical College, Bombay; Robert John Harley-Mason, Middlesex Hospital; Arthur Ernest Williams Idris, University College; Thomas Herbert Williams Idris, Middlesex Hospital and University College; George Gerald Jack, Middlesex Hospital; David William Jones, Kenneth John Taylor Keer, Reginald Hutchinson Lucas, and William Kellock McKay, Guy's Hospital; Oscar Gladstone Maginness, St. Bartholomew's Hospital; Edward Hillis Marshall, King's College; Reginald Victor Martin, St. Mary's Hospital; Arthur Wellington Matthew, London Hospital; Kavasji Cursetji Mulla-Firoze, L.M.S. Bombay, Grant Medical College, Bombay; Henry Barton Owens, London Hospital; John Hayward Paget, Charing Cross Hospital; William Percivall Penhale, Middlesex Hospital; Claude Hollingworth Philips, London Hospital; William Piper, Westminster Hospital and King's College; Francis Charles Robbs, St. Mary's Hospital; George Marsden Roberts, St. Bartholomew's Hospital; Granville Douglas Robertson, St. Mary's Hospital; Anthony Wellesley Monckton Sawyer, University College; Bernard Edward Patrick Sayers, Middlesex Hospital; Kenneth Vickerman Smith, Charing Cross Hospital; Thomas Victor Somerville, London Hospital; William Collis Spackman, Birmingham University; Mackenzie Thwaites Wills Steedman, B.A. Cantab., Cambridge University; Harman Taylor, Manchester University; Horatio Thomas, B.Sc. Lond., University College, Cardiff; Charles Alexander Weller, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; and Cecil William Wilson, London Hospital.

At the First Professional Examination, held on Sept. 27th, 28th, 29th, and 30th, the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—Errington Atkinson, Percival Cheal, and George Stanley Deane, London Hospital; Gloster Tyndall Garraway and George Harris Haines, University College; Brabazon James Hallowes, St. Bartholomew's Hospital; Jagan Nath Puri, London Hospital; Gordon Stuart Terry, Bristol University; and Karl Johan Fredrik Westman, Brighton Technical College.

Chemistry.—Kanshi Ram Batra, University College; Joseph Herbert Bayley, London Hospital; Oliver St. Leger Campion, Dulwich College; Cyril James Gozney Exley, Leeds University; Moustafa Fahmy, London Hospital; Lancelot Horsley, Birkbeck College; Ernest Gwyn Howell, University College, Cardiff; James Stuart Leslie and Alexander Joseph Vincent McDonnell, London Hospital; Arthur Rennie Muir, University College, Cardiff; Mian Mohammad Shaffi, London Hospital; Ramon Romero Sy-Quia, London Hospital and City of London College.

Physics.—John Behesnilian, Charing Cross Hospital; Robert Edmund Barry Denny, London Hospital; Frederick Ernest Feilden, Middlesex Hospital; Luis Hernando Garces, London Hospital; Henry Judson Grimshaw, Liverpool University; and Herbert Henry Silley, King's College.

Biology.—John Andrew, South-Western Polytechnic; Wilfred Angel Easton, Guy's Hospital; Samuel Mallinick, Halle University and London Hospital; (Miss) Lily Fanny Pain, Royal Free Hospital; David John Platts, King's College; Jagan Nath Puri, London Hospital; Bryan Montague Tuke, Middlesex Hospital; and Karl Johan Fredrik Westman, Brighton Technical College.

At the quarterly examination in Practical Pharmacy held on Oct. 6th the following gentlemen were approved:—

Arthur Brodie Hamilton Bridges, St. Thomas's Hospital; Stacey Archer Burn, St. Bartholomew's Hospital; Roderick Ernest Clarke, King's College Hospital; Edward Robert Cecil Cooke, B.A. Cantab., Cambridge and Sheffield Universities; William Lewis Cowardin, St. Mary's Hospital; Edward Percy Drabble, London Hospital; Harry Dudley, University College; Philip Cuthbert Collingwood Fenwick, St. Thomas's Hospital; Alfred George Timbrell Fisher, Bristol University and St. Bartholomew's Hospital; Andrew Alexander Fyffe, Sheffield University; Alfred Linton Gardner, Guy's Hospital; Ernest Richard Gordon Greville, St. Thomas's Hospital; Frank Mainwaring Hughes, London Hospital and private study; Samuel Hutchinson, University College Hospital; Anthony Kennedy, B.A. Cambridge, Cambridge University, and Middlesex Hospital; Claude Jocelyn Delabere May, Bristol University; Douglas Duncan Malpas, Middlesex Hospital; Herbert Henry Powys Morton, King's College Hospital; Henry Maurice Peacock, L.D.S. Eng., private study; Edmund Uniacke Russell, King's College Hospital; Henry Wakeman Scott, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Gerald Nicholson Stathers, Cambridge University and St. Bartholomew's Hospital; William Vere Taylor Styles, Middlesex Hospital; Cedric Norman Vaisey, Bristol University; Percival Dillon Warburton, Sheffield University; James Anderson Watson, Otago University and Middlesex Hospital; Kim Gien Wee, St. Thomas's Hospital; and William Neville Pennant Williams, Liverpool University and private study.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery, held on Sept. 27th, 29th, and 30th, the following gentlemen were approved:—

Chemistry and Physics.—Norman Mulliner, Liverpool University; Charles Justin O'Callaghan, Charing Cross Hospital; and John Stanley Palmer, Birkbeck College.

Chemistry.—Philip Blake and Robert Campbell, Charing Cross Hospital; Oliver Nettleton Dadley, Municipal School, Gloucester; and Harold John Stickland, Birkbeck College.

Physics.—Herbert Howard Cooke, Wandsworth Technical Institute; and Walter Alexander Crane, Liverpool University.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Biology and Chemistry.—W. Fox, Charing Cross Hospital.

Materia Medica and Pharmacy.—J. E. S. Sheppard-Jones, St. Thomas's Hospital.

Anatomy.—A. Barry, London Hospital; H. H. Fairfax, Charing Cross Hospital; and G. L. Lawlor and R. V. Martin, St. Mary's Hospital.

Physiology.—A. Barry, London Hospital; J. F. Bourke, Glasgow; and A. E. Bullock, G. L. Lawlor, and R. V. Martin, St. Mary's Hospital.

UNIVERSITY OF GLASGOW.—The following have satisfied the examiners in the fourth (final) professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.):—

Mary Alexander, M.A., Robert Richmond Archibald, M.A., B.Sc., John Atkinson, Robert Blackie Austin, James Alexander Stewart Burges, Thomas Simpson Campbell, B.Sc., Robert Hunter Deans, Louisa Emma Dodge, Peter Drummond, William Deanburn Dunlop, Andrew Scobie Findlay, Thomas Scott Forrest, Alexander Fraser, Nicolas Gebbie, John Gray, Archibald Campbell Haddow, John Reid Haldane, William Hamilton, James Hendry, M.A., B.Sc., James Jack, James Macallan, Donald Christopher Macdonald, Alastair Macintyre, Balfour M'Kean, John Gladstone Mackenzie, Thomas Jones Mackie, Andrew Bruce MacLean, William Alexander MacLennan, Alexander Thomson M'Whirter, Frank Needham Marsh, Campbell Lamont Miller, M.A., Andrew Ross Muir, Clark Nicholson, M.A., John Paterson, Thomas Paterson, Richard Reid Kirkwood Paton, John Penman, James Francis Quigley, Rutherglen, Daniel Wright Ritchie, John Ivison Russell, Margaret Elizabeth Rutherfurd, Florence Elizabeth Sexton, James David Speid Sinclair, Gilbert Innes Strachan, John Norman Macdonald Sutherland, William Oswald Taylor, Stephen Veitch Telfer, and Henry Yellowlees.

The following passed with distinction in the subjects indicated:—

In (*a*) Surgery and Clinical Surgery, (*b*) Practice of Medicine and Clinical Medicine: Thomas Jones Mackie. In Surgery and Clinical Surgery: Robert Hunter Deans and Andrew Ross Muir. In Midwifery: James Hendry, M.A., B.Sc., James Jack, Donald Christopher Macdonald and Balfour M'Kean.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. Carl Prausnitz, who has been doing bacteriological work in London, has been appointed Assistant in the University Institute of Hygiene with special charge of the section for the Treatment of Rabies.—*Catania:* Dr. Francesco Francariglia has been promoted to the Professorship of Ophthalmology. Dr. Francesco Caruso has been appointed Extraordinary Professor of Midwifery and Gynæcology.—*Clausenberg:* Dr. F. Veress has been recognised as *privat-docent* of Dermatology.—*Copenhagen:* A new Royal Hospital has recently been opened containing 40 wards. There are also four new university institutes—viz., the Pathological Anatomy Institute under Professor Fibiger, the Pharmacological Institute under Professor Bock, the Pharmaceutical Institute under Professor Pontopidan, and the General Pathology Institute under Professor Salomonsen.—*Erlangen:* Dr. Robert Heinz, *privat-docent* of Pharmacology, has been promoted to an Extraordinary Professorship.—*Florence:* Dr. Cesare Frugone has been recognised as *privat-docent* of Medical Pathology, Dr. Giuseppe Zironi as *privat-docent* of

Surgical Pathology, and Dr. Carlo Francioni as *privat-docent* of Pædiatry.—*Freiburg:* Dr. Karl Hegar, *privat-docent* of Midwifery and Gynæcology, has been granted the title of Extraordinary Professor.—*Genoa:* Dr. Attilio Catterina, Extraordinary Professor of Operative Medicine, has been promoted to the Ordinary Professorship.—*Göttingen:* Dr. W. Heubner, Extraordinary Professor of Pharmacology, has been promoted to the Ordinary Professorship.—*Greifswald:* Dr. Fritz König of Altona has been offered the chair of Surgery vacated by Professor Payr, who is going to Königsberg.—*Innsbruck:* Dr. Fritz Pregl, Extraordinary Professor in the University of Gratz, has been appointed to the chair of Medical Chemistry, in succession to Dr. Löbisch, resigned.—*Königsberg:* Dr. Payr of Greifswald has been appointed to the chair of Surgery in succession to Dr. Lexer, who is going to Jena.—*Marburg:* Dr. P. Ostmann has been promoted to an Honorary Professorship of Otology.—*Modena:* Dr. Carlo Ferrai has been promoted to the chair of Forensic Medicine.—*Munich:* Dr. A. Schmincke of Würzburg has been recognised as *privat-docent* of Anatomy.—*New Orleans* (*Tulane University*): Dr. Robert P. Bean has been appointed Adjunct Professor of Anatomy.—*Padua:* Dr. Arturo Carraro has been recognised as *privat-docent* of General Pathology, Dr. Rodolfo Vigliani as *privat-docent* of External Pathology, and Dr. Enrico Ronzani as *privat-docent* of Hygiene and Sanitation.—*Pisa:* Dr. E. Arman has been recognised as *privat-docent* of Dermatology.—*Prague* (*German University*): Dr. Hans Rubirtius has been recognised as *privat-docent* of Surgery.—*Rome:* Dr. Achille Capogrossi has been recognised as *privat-docent* of Medical Pathology, Dr. Gustavo Modena as *privat-docent* of Neurology and Psychiatry, and Dr. Antonino del Piano as *privat-docent* of Pædiatry.—*Sassari:* Dr. Mario Pelagatti has been promoted to the Ordinary Professorship of Dermatology.—*St. Petersburg* (*Women's Medical Institute*): Dr. Shirshoff, of the Military Medical Academy, has been appointed Professor of Midwifery and Gynæcology.—*Vienna:* Dr. Friedrich Dimmer of Gratz has now accepted the chair of Ophthalmology, which at first he declined.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The following were the winners of scholarships at this school: University Scholarship: Michael Joseph Petty, Downing College, Cambridge. Preliminary Science Scholarships: 1st, A. L. Blunt, St. Thomas's Hospital Medical School; 2nd, C. O. H. Jones, Technical Institute, Walthamstow. Merchant Taylors' Scholarship: Cyril George Learoyd.

DONATIONS AND BEQUESTS.—In response to the appeal which was made in July last Mr. Otto Beit has promised a gift of £5000 to complete the amount needed for the erection of the Children's Sanatorium (Consumptive Children) at Holt, Norfolk.—Among other large bequests the late Mr. W. Bell of Bootle has left £1000 to each of the following institutions: the Bootle Borough Hospital; the David Lewis Northern Hospital, Liverpool; the Royal Southern Hospital, Liverpool; the Stanley Hospital, Kirkdale, Liverpool; the Liverpool Royal Infirmary; and the Liverpool Blind Asylum. He also left £1000 to the Liverpool University.

THE SALE OF POISONS.—At the Eastbourne county court on Oct. 6th the Pharmaceutical Society was successful in recovering in two distinct cases the penalty of £5 for a breach of the Poisons and Pharmacy Act, 1908. On behalf of the society a purchase was made at a shop at Eastbourne, where the business of a seedsman and florist is carried on, of a bottle of XL All Insecticide. The sale was made by a lady assistant. The proprietor of the shop holds a licence under the local authority, but the assistant did not. In the other case a Hailsham defendent sold a poison used for fumigating purposes in a bottle which did not bear the necessary labels. It was held for the defence that it was an error of an assistant, but Judge Scully, in giving judgment for the Pharmaceutical Society, said "these little mistakes would occur." The Poisons and Pharmacy, 1908, came into force on April 1st, 1909. It provides better safeguards than heretofore existed against the sale of poisons used for medicinal purposes, and extends the facilities for obtaining poisonous compounds used in horticulture and agriculture. In connexion with the latter class of poisons there are, of course, certain regulations which must be complied with as a precautionary measure, so that, in so far as it is possible, deaths from accidental poisoning may be avoided. And the importance of these regulations can be gauged from the fact that in the case of the XL All Insecticide the particular bottle sold at Eastbourne contained sufficient to poison 70 persons, while in the other case the fumigating material contained no fewer than 300 poisonous doses.

DAWLISH COTTAGE HOSPITAL.—Mrs. Nosworthy of Dawlish has given £1000 to the funds of the local cottage hospital. Mrs. Nosworthy gave a similar sum to the institution in 1907.

AT the last meeting of the Buckfastleigh (Devon) urban district council the resignation was accepted with very much regret of Mr. Henry Ubsdell, M.R.C.S. Eng., L.S.A., who has been medical officer of health for the past 35 years.

LONDON HOSPITAL MEDICAL COLLEGE.—The following entrance scholarships have been awarded:—Price Entrance Scholarship in Science (value £120), A. C. Perry. Entrance Science Scholarship (value £60), P. C. Cloake. Entrance Science Scholarship (value £35), S. Batchelor. Epsom Scholarship (value £126), J. N. Deacon. Price Scholarship in Anatomy and Physiology (University Scholarship, value £60), H. H. Mathias (King's College, Cambridge).

UNIVERSITY OF LONDON.—The pass-list of the September matriculation examination of this University shows that 99 students were successful in the first division and 273 in the second division. The results of the June matriculation examination for the colonies show that 12 candidates from Ceylon have passed, 9 from Newfoundland, 2 from Queensland, 2 from Penang, and 1 each from British Guiana, Antigua, Seychelles, and Barbados.

MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.—The London County Council on Oct. 11th approved arrangements with the Poplar Hospital for Accidents and a local committee in Deptford for the dental treatment of school children as recommended by the Education Committee before the summer recess. The proposal to renew the experimental scheme for the treatment by the "Queen's" nurses of children suffering from suppurating ears in the Paddington instead of the Hackney district was approved. The Finance Committee remarked that the apparent failure of this experiment in two districts raised the question of the general efficacy of the policy, and as to this the Education Committee had been asked to give further particulars.

THE FEES OF DISTRICT MEDICAL OFFICERS: DISCUSSION AT THE METROPOLITAN WATER BOARD.—At its meeting on Oct. 7th the Metropolitan Water Board had under consideration a report presented by the works and stores committee dealing with the regulations governing the duties of district medical officers in the Board's service. The committee, it was stated, had carefully investigated the operation of these regulations so far as they affected the fees to be paid for attendance in cases of accidents to the Board's workmen whilst on duty. As a result of its deliberations the committee recommended that the fee to be paid in accident cases should be 3*s.* 6*d.* in respect of each attendance, except in special and serious surgical cases, in which a higher fee might be justified. In the latter event the Board's chief medical officer should be entrusted with the duty of considering the charges made by the district medical officer, and advising whether such fees were reasonable. Dr. R. M. Beaton (L.C.C.) objected to the method in which the proposed alterations had been presented to the Board. A copy of the regulations should have been circulated amongst the members so that they might have had an opportunity of studying the question, which was intimately connected with the health of the Board's workmen. If the matter were not pressing he hoped the chairman of the committee would consent to postpone it for a month, and in the meantime circulate the regulations. Mr. C. E. Hearson (Camberwell Borough Council) (chairman of the committee) hoped Dr. Beaton would not press his request, because there was nothing hidden behind the committee's report. It referred almost entirely to regulations which had been previously passed by the Board, and the committee had only arranged them in consecutive order, so that they constituted more readable matter for medical men. The only difference that was being made was in regulating the fee for surgical

cases. A subcommittee had carefully considered the whole question with the assistance of the Board's chief medical officer, Dr. R. J. Collie, and it was only in cases where there had been a very serious accident, which required more work than usual, that Dr. Collie would be invited to consider what was a fair fee. The committee's object had been to regulate the charges in surgical cases. In medical cases the fees had been previously passed by the Board and no change was proposed. Dr. Beaton said he entertained no doubt that the question had been carefully considered, and the work was probably well done, but the committee had no right to present to the Board mere strips of information, which they were expected to accept without comment, and when no other facility for investigation than that a member interested should be compelled to ask for a copy of the new regulations. It was against that he protested, and not against the wisdom of the regulations. Mr. Hearson expressed his willingness to defer the whole matter if that were the pleasure of the Board, but repeated that it was only in connexion with the fees for serious accidents that Dr. Collie would be consulted, in case any excessive charge were made by the district medical officer. The fee of 3*s*. 6*d*. for each attendance would be paid in all ordinary cases. The chairman of the Board intimated that the question had been very fully considered in committee for many hours, and was only presented to the Board for formal approval. Dr. Beaton thereupon withdrew his request for postponement, and the committee's recommendation was agreed to.

SOCIETY OF OFFICERS OF "INFANT CONSULTATIONS."—A meeting was held in the summer at the Marylebone Dispensary, 77, Welbeck-street, London, W., to consider the advisability of starting a society consisting of those interested in the work of "infant consultations." The following resolutions were put to the meeting and carried unanimously, subject to amendment at the general meeting to be held on Oct. 19th at 6 P.M. :—

1. That a Society of Officers of "Infant Consultations" be and is hereby constituted.
2. And that the aim and object of such society be to: (*a*) Bring into closer relationship all those engaged or interested in the work of such institutions. (*b*) To promote the establishment of similar institutions and to advise as to their organisation. (*c*) From time to time to hold meetings for the reading of papers and the holding of discussions on subjects germane to the work of "infant consultations." (*d*) For the recording of experience gained by individuals engaged in the work. (*e*) For the collection of literature, statistics, and reports bearing on the subject.
3. That the society consist of a president, vice-president, honorary secretaries, treasurer, librarian, and ordinary members.
4. That the expenses of the society be defrayed by an annual subscription of 2*s*. 6*d*.

An executive committee has already been formed. All communications should be addressed to the honorary secretaries, Dr. H. Ronald Carter, 11, Leonard-place, Kensington, London, W., and Dr. J. Lane-Claypon, 69, Prince of Wales Mansions, Battersea Park, London, S.W.

APPOINTMENT OF ASSISTANT TO THE LIVERPOOL MEDICAL OFFICER OF HEALTH: A NEW DEPARTURE.—Dr. W. L. Hawksley has been recently appointed by the health committee of the Liverpool city council to the new post of assistant medical officer, with special reference to dealing with tuberculosis. There were a large number of applicants, 58 in all, many of them possessing the highest qualifications. It so fell out that there was no better candidate than a local one, Dr. W. L. Hawksley, whose claims lay in the fact that he had held appointments in the David Lewis Northern Hospital and the Liverpool South Dispensary, from which latter institution he was transferred to take charge of the special tuberculosis wards of the corporation at Fazakerley Hospital. After nearly two years' experience there he was appointed one of the school medical officers. In all these posts he had worked well, and these circumstances led to his well-deserved promotion. The duties of the new assistant to Dr. E. W. Hope (medical officer of health) are to visit the homes of persons suffering from tuberculosis who have been in-patients at Fazakerley Hospital or notified under the order of the Local Government Board, with a view to ascertain that medical instructions are being followed and to remind or advise the patient when necessary, as to the precautions to be observed. He will be required to note and report to the medical officer of health any home conditions likely to influence the disease, either in regard to the patient or to those living with him or her. He will also be required to keep systematic records of visits or re-visits and of the conditions found, and to submit them to the medical officer of health, and to carry out any other kindred duty or investigation which the health committee may direct.

A CASE of cholera, presumably cholera nostras, has proved fatal at the Royal Free Hospital.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—The inaugural address, "Le Rheumatisme Tuberculeux" of Poncet of Lyons, will be delivered by Dr. H. Alexis Thomson on Oct. 19th, at 64, St. James's-street, at 8.30 P.M.

THE annual dinner of the Westminster Hospital and Medical School took place on Thursday, Oct. 6th, at the Imperial Restaurant. Mr. W. Vaux Graham, vice-chairman of the hospital, presided. A large number of past and present Westminster men attended, and a most enjoyable evening was spent. The dean reported favourably on the present condition of the school.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The council has decided to admit two medical practitioners possessing the Diploma in Public Health gratuitously for a period of six months each in order to afford them the opportunity for a more extended experience in bacteriological methods. Applications should be forwarded to the Principal, 37, Russell-square, W.C.

THE ROYAL EYE HOSPITAL, ST. GEORGE'S CIRCUS, SOUTHWARK.—At the School of Ophthalmic Surgery and Medicine, connected with this institution, on Friday, Oct. 21st, at 5.15 P.M., a lecture will be given by Mr. J. Stroud Hosford, F.R.C.S. Edin., assistant surgeon to the hospital and assistant ophthalmic surgeon to the Temperance Hospital, London. The subject of the lecture will be "Some Points in the Diagnosis of Orbital Disease."

ROYAL SANITARY INSTITUTE CONGRESS, BRIGHTON.—The sanitary committee of the Brighton town council has placed on record its appreciation of the valuable services rendered to the town by Dr. Duncan Forbes, medical officer of health, as honorary secretary of the local committee entrusted with the arrangements for the successful congress of the Royal Sanitary Institute held at Brighton in September.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Oct. 6th, with Sir Francis Champneys in the chair. A letter was considered from the medical staff of the Royal Derby and Derbyshire Nursing Institution as to the suspension of the institution as a training school for midwives. It was announced that the chairman, after an interview with Dr. F. R. Cassidi, one of the medical staff of the Royal Derby and Derbyshire Nursing Institution, had reported that the institution had been since July 28th in a position to train pupils according to the rules of the Board. It was decided that the report of the chairman be adopted. Letters (addressed to the chairman) were read from Mrs. Dugdale of Meeson Hall, Wellington, Salop, as to the subsiding of midwives in sparsely populated rural districts. Mrs. Dugdale wished to ascertain whether steps were to be taken in the near future by the State to subsidise midwives in sparsely populated districts. She gave details of the difficulties encountered in raising money for the maintenance of nurses, and stated that after 12 years' experience she found it impossible to collect the necessary funds, and she was forced to the conclusion that a State subsidy was the only means of getting over the difficulty. In her opinion the money required should not be left to individuals to provide. The chairman stated he had written to Mrs. Dugdale saying what the Central Midwives Board had done in sympathy with this movement. Mrs. Dugdale, in replying, said her object was to emphasise the necessity for helping midwives to make a living in sparsely populated districts, otherwise the midwives must make for the towns. In the country parts known to Mrs. Dugdale the medical men had never failed when called upon for help. The Board decided that copies of the previous resolutions on the subject be sent to Mrs. Dugdale. A letter was received from Miss Bernard-Boyce, inspector of midwives for Norfolk, stating that the local supervising authority for that county had now determined

that in no case should a period of suspension of a midwife exceed the term of seven days. An application from the Norwich Maternity Charity to hold the written examination locally at Norwich was considered. The Board decided that it be not granted for the present and that the applicants be informed that they may renew their application when there is a prospect of a larger number of candidates.

UNIVERSITY COLLEGE, LONDON.—The following awards of entrance scholarships and exhibitions to the Faculty of Medical Sciences at University College, London, have been made: Bucknill Scholarship and First Medical Exhibition (value of 190 guineas), divided equally between Mr. W. A. E. Karunaratne and Mr. C. J. H. Sharp. Second Medical Exhibition (value of 55 guineas), Mr. H. A. Fawcett; *proxime accessit*, Mr. E. A. L. Sansom. Epsom Scholarship, Mr. H. Ll. G. Hughes.—The Page May Memorial Lectures in Physiology will be delivered at the College on the following Mondays and Tuesdays at 4.30 P.M.: Oct. 24th and 25th, Nov. 7th, 8th, 28th, and 29th. The first course dealing with Neurology will be delivered by Professor C. S. Sherrington of the University of Liverpool. A syllabus can be obtained on application to the secretary of University College.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE.—A meeting of the General Committee of this Congress was held on Wednesday, Oct. 12th, in the library of the Royal College of Physicians of London, under the Presidency of Sir Thomas Barlow. It will be remembered that an advisory board was appointed on Feb. 7th to nominate the officers of the Congress. The report of this board was put before a representative meeting, with the result that Sir Thomas Barlow was elected President, and Dr. W. P. Herringham Secretary. Both elections, made on the proposal of the advisory board, were unanimous. Sir Thomas Barlow, in returning thanks for his election, owned that he wished that he could have escaped the grave responsibility, while Dr. Herringham pointed out to the meeting how enormously he and all interested in the Congress were indebted to the work and zeal of Mr. D'Arcy Power, formerly secretary to the general committee. The advisory board had proposed "that there should be two Treasurers of the Congress, of whom one should be a layman of high financial position, and the other an eminent medical man." The principle of two treasurers was adopted by the meeting, but it was resolved that both should be medical men. The nomination by the board as one of these treasurers of Mr. G. H. Makins was unanimously adopted; the choice of the second treasurer will be made by the executive committee. A large organising committee was then formed by resolution, with directions to select a small executive committee.

BOOKS, ETC., RECEIVED.

ALEXANDER (VAN) AND CO., 31, Craven-street, London, W.C.

Radio-activity. A Brief Guide to its Use in General and Specialist Practice. Compiled by Guy Stephen, D.P.H. Lond., Officier de Santé (France). Price 1*s*.

DOUGLAS, NOBLE'S ISLE OF MAN GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon, unmarried. Salary £90 per annum, with board and washing.

DUBLIN, DR. STEEVENS' HOSPITAL.—Honorary Anæsthetist.

FRENCH HOSPITAL, 172, Shaftesbury-avenue, W.C.—Resident Medical Officer, unmarried. Salary £50 per annum, with board and laundry.

GLASGOW DISTRICT ASYLUM, Woodilee, Lenzie.—Assistant Medical Officer. Salary £125 per annum, with board, lodging, washing, &c.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway, N.—Surgeon.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50, with board, residence, and laundry.

HALIFAX UNION POOR-LAW HOSPITAL.—Resident Medical Officer. Salary £110 per annum, with apartments, rations, and washing.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with rooms, board, and washing.

IPSWICH, BOROUGH OF.—Assistant Medical Officer of Health. Salary £250 per annum.

KING EDWARD VII. SANATORIUM, Midhurst, Sussex.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and attendance.

LISCARD, WALLASEY DISPENSARY AND VICTORIA CENTRAL HOSPITAL, Cheshire.—House Surgeon, unmarried. Salary £100 per annum, with apartments, board, attendance &c.

LIVERPOOL MEDICAL MISSION.—Assistant Medical Officer. Salary £150 per annum.

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £100 per annum, with rooms, attendance, board, and washing.

MANCHESTER, ANCOATS HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board, &c.

MANCHESTER ROYAL INFIRMARY.—Medical Officer for six months. Salary at rate of £100 per annum, with board and residence.

MARGATE, ROYAL SEA BATHING HOSPITAL FOR SURGICAL TUBERCULOSIS.—Resident Surgeon. Salary at rate of £80 per annum, with board and residence.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood.—Honorary Dental Surgeon.

NEW HOSPITAL FOR WOMEN.—Two House Surgeons, Senior Assistant and a Clinical Assistant for Ophthalmic Department, and Clinical Assistant for Tuesdays (all females).

NEWCASTLE-UPON-TYNE CITY ASYLUM, Gosforth.—Junior Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, and laundry.

NORWICH CITY ASYLUM, Hellesdon-next-Norwich.—Assistant Medical Officer, unmarried. Salary £150 per annum, with rooms, board, and laundry.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Assistant House Surgeon for six months. Salary £20, with board, lodging, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Honorary Dental Surgeon.

PENDLEBURY, MANCHESTER CHILDREN'S HOSPITAL.—Visiting Surgeon. Salary £100 per annum.

PRESTON ROYAL INFIRMARY.—Senior and Junior House Surgeons, unmarried, for six months. Salaries £80 and £60 per annum, with board, residence, and washing.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Assistant Surgeon. Also Junior House Surgeon and Junior House Physician for six months. Salary £40 per annum in each case, with board, residence, and laundry.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Assistant Physician. Also Assistant Surgeon.

ROYAL GENERAL DISPENSARY, 25 and 26, Bartholomew Close, E.C.—Physician. Salary £40 per annum.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—Resident Medical Officer for six months. Salary at rate of £120 per annum, with board, lodging, and washing.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Resident House Surgeon, unmarried, for six months. Salary £100, with board, residence, and washing.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Commissions.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—House Surgeon. Salary at rate of £50 per annum, with board, residence, and laundry. Also Pathologist and Curator. Salary £50 per annum.

ST. ALBANS, HERTS COUNTY ASYLUM, Hill End.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging, washing, &c.

ST. MARY'S HOSPITAL, Paddington, W.—Casualty Physician. Salary £75 per annum.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Senior Resident Medical Officer, unmarried. Salary at rate of £100 per annum, all found.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon for six months. Salary £80 per annum, with board, residence, and laundry.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.

TEIGNMOUTH HOSPITAL, South Devon.—House Surgeon. Salary £80 per annum, with board, lodging, and laundry.

TIVERTON INFIRMARY AND DISPENSARY.—House Surgeon and Dispenser. Salary £80 per annum, all found.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Physician for Diseases of Women. Also Anæsthetist.

WESTMINSTER GENERAL DISPENSARY, 9, Gerrard-street, Soho, W.—Resident Medical officer. Salary £120 per annum, with rooms, gas, coal, &c.

WESTMINSTER HOSPITAL.—Medical Officer in charge of Electrical Department. Salary £120 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

KILLICK.—On Oct. 7th, at Trinity House, Maidstone, the wife o Charles Killick, M.D., F.R.C.S., of a son.

POLLARD.—On Oct. 4th, at Harpur-place, Bedford, the wife of H. Dean Pollard, M.B., B.S., F.R.C.S., of a son.

MARRIAGES.

HAWKSLEY—BENSON.—On Oct. 7th, at Deeping St. Nicholas Parish Church, Lincolnshire, by the Rev. W. M. Benson, assisted by the Rev. S. Skene and the Rev. E. P. Cook, M.A., Walter Linney Hawksley, of Liverpool, eldest son of the late Dr. and Mrs. Hawksley, of Southport, to Annie Gertrude, youngest daughter of the Rev. and Mrs. W. M. Benson, Deeping St. Nicholas.

UPCOTT-GILL—BIRT.—On Oct. 4th, at St. Etheldreda's, Hatfield, Herts, Geoffrey A. Upcott-Gill, F.R.C.S., to Constance Mary, only daughter of Sir William and Lady Birt.

DEATHS.

FRASER.—On Oct. 7th, at Borthwickbrae, Hawick, N.B., suddenly, Frederick William Dyce Fraser, M.D., aged 55 years.

LEAF.—On the 5th inst., at Eastbourne, Cecil Huntington Leaf, F.R.C.S., of 75, Wimpole-street, W., son of the late Frederick H. Leaf, of Streatham.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"IMITATIVE SUICIDE."

THE subject of imitative suicide has recently attracted attention in the public press. The mental condition of an individual who commits suicide is difficult to fathom. In one class of case a person will fancy that he is being constantly persecuted, that he is always watched, or that he is financially ruined—all these ideas being contrary to fact; he destroys himself in order to escape these imaginary evils. Such a man is obviously of unsound mind. In another class of case a man has committed a crime or disgraced himself in some way, and in order to free himself from the consequences of his act he takes his own life in preference to facing exposure or the punishment entailed. Such an individual is not necessarily insane. But there is yet another class—people who are subject to attacks of depression and who are apt to brood over real or imagined injuries. These are "weak-minded," or may be on the "border line" between sanity and insanity. Or another class likely to act upon some sudden impulse are the alcoholics. In these a passing suggestion is likely to result in some deed of violence often of a suicidal nature. Such impulses are susceptible of being spread by imitation. Reading in the newspaper of a mode of self-destruction which is likely to excite great notoriety has been known to induce a similar act in the reader; a suicide by coal-gas, especially when a description has been given of the exact manner in which the deed was carried out, has found imitators. More particularly, however, the sight of a particular spot or locality where previous suicides have taken place may induce a person, who may hitherto have been unsuspected of any such disposition, to destroy himself. Falls from heights especially come under this heading. Numerous suicides have taken place from the Suspension Bridge at Clifton. A writer in the *Yorkshire Evening News* has recently said that much harm is done by pictures and descriptions, and that imitative suicide may follow. We agree with him that the necessary suggestion may be evolved by such means. The suggestion may act on the conscious mind or the subconscious. Numerous instances are on record of alcoholics who have attempted to destroy themselves by throwing themselves from buildings and the like, and have subsequently retained no recollection of the event. The mere fact of being at a height suggested the act of throwing themselves over, and the action immediately followed the idea, as is so often the case in such individuals. These cannot always be considered as "imitative," but in some cases they are possibly of that nature.

A QUESTION OF FEES.

To the Editor of THE LANCET.

SIR,—One so often hears the poor general practitioner accused by the "heads of the profession" of lacking in that nice conception of medical etiquette in his dealings with his professional brethren which obtains amongst the army of consultants that I am tempted to ask you to record a recent experience of mine at the hands of one of these superior persons.

As I was travelling by train in the provinces I had the misfortune to get a piece of grit from the engine impacted in my cornea. On arriving at one of our largest cities I found that the eye was causing me much pain, and was advised by a non-medical friend who knew the town to go to an ophthalmic dispensary near at hand. I went there, but found that the house surgeon was not resident and had left. The attendant directed me to the house of Dr. ——, who holds a position on the staff of the chief hospital in the city.

On being ushered into "the presence" I explained that I was a general practitioner from a neighbouring county, and, apologising for troubling him, asked him to remove the offending particle. He replied that it was no trouble, cocainised the eye, removed the grit, instilled atropine, and applied a bandage. I thanked him, and, though rather afraid of insulting him by the question, asked what was his fee. To my surprise he at once replied, "*One* guinea." The accent upon the numeral plainly intimated that this was a concession, and that had I been a layman the charge for this major operation would have been two at least. Not being an argumentative person, I paid at once and departed, "shaking the dust from off my feet as a testimony against him."

I am confident that no general practitioner would have made any charge for similar services rendered to a professional brother, whether a stranger or no. We may have our shortcomings, but we observe the old proverb, "Hawks don't pick out hawks' een," in treating our ailing brethren.

I am pleased to see from the "Medical Directory" that the operator lectures to the students of his hospital on ophthalmology and not on medical ethics.

I enclose my card and sign myself, yours faithfully,

Oct. 4th, 910. M.B., F.R.C.S.

HEALTH IN WEST AFRICA.

IN our issue of Oct. 1st, p. 1053, we published an abstract of the report to the Colonial Office on Health and Sanitation in Sierra Leone in which was noted the great improvement in sanitation that is taking place in our West African colonies. We have now received the *West African Annual* for the year 1910 which contains the record of a journey to Liberia and our colonies at Sierra Leone, the Gold Coast, and Southern Nigeria made at the end of last year on behalf of the *African World*. By means of pen and camera an attempt is made to give the reader an idea of the developments now going forward in these colonies. Under the heading "The Health Factor and its Bearing on Economics" a well-deserved tribute is paid to the "measures which are due to Sir Patrick Manson, Major Ronald Ross, and Dr. the Hon. W. T. Prout, and the splendid band of men who have promulgated and enforced them throughout the whole length of British West Africa." In an interview at Lagos with Dr. J. Arthur Pickels some interesting information is given with regard to the health conditions at that place. These have greatly improved during recent years owing to the filling up of swamps, the methodical crusade against mosquitoes, the free distribution of quinine, and the more exact medical knowledge and better appreciation by laymen of the personal care of their health. Dr. Pickels points out that the mortality is markedly less than formerly in the large towns, that various comforts so useful to medical men when prescribing for an invalid are now easily obtainable, and that the sanitation of the town has greatly improved under the care of the municipal board, of which the principal medical officer, Mr. W. H. W. Strachan, C.M.G., is chairman. The making of good roads, which give free passages for fresh air, and the removal of cul-de-sacs and narrow winding lanes have also greatly helped towards healthier conditions. With regard to the native attitude towards European medical men, Dr. Pickels says that although there was at one time an attitude of suspicion and unwillingness to place themselves under treatment, the people are now beginning to take a more enlightened view. The native doctors having charge of the Government dispensaries in the town have helped to bridge over the feeling of distrust of the medical profession which formerly existed in the minds of the natives. In an interesting description of the Lagos Hospital it is stated that the institution is made up of a number of bungalows specially built on an island site, surrounded by a wall which makes the place quite a little village by itself. The European ward is situated in a stone bungalow which contains ten beds. One ward is used mainly for the military and the police, who are kept together for convenience in inspection by their own officers. Another ward for female natives contains eight beds. There is a completely equipped operating theatre, and the services of native female nurses are utilised in the hospital. The institution is a Government one and is open to everybody, but Europeans and natives able to afford it pay according to their means. The *Annual*, which is published by the African World, Limited, Throgmorton House, Copthall-avenue, London, E.C., at the price of 1*s*., contains a good map, is well illustrated, and supplies a great deal of useful information not only to those who intend to visit West Africa, but to those at home who wish to make themselves acquainted with the conditions of life in a not unimportant part of the British Empire.

USEFUL DIARIES.

FROM the Cambridge University Press has come a useful little diary, the Cambridge Pocket Diary for 1910–1911, beginning, that is, in the last week in September of 1910, and running to September 30th, 1911, covering, therefore, the academical instead of the calendar year. The diary will easily go into the waistcoat pocket and costs only 1*s*. or can be obtained with a pencil and stamp pocket added for 2*s*. The same firm is also publishing a block-form diary of the academical year, each page of which contains seven days, the printed matter being arranged on the left hand half of the sheet, ample space being left on the right for manuscript notes for engagements.

HEALTH IN THE TONGA OR FRIENDLY ISLANDS.

A PROTECTORATE over these islands, situated in the Southern Pacific, 390 miles to the East-south-east of Fiji, was proclaimed in May, 1900. According to the latest report received at the Colonial Office from the British Agent and consul, Mr. W. Telfer Campbell, the population at the end of 1909 was estimated at 21,958. In the year 1909 there were 293 births and 267 deaths. The most prevalent disease is yaws. Native children are expected to go through an attack as a matter of course. If a child be lucky enough to escape its relatives consider that it will not be healthy. Dysentery and enteric fever occur occasionally, but are not so prevalent as might be expected in view of the primitive sanitary arrangements. Cases of leprosy are scattered throughout the group. The question of setting an island apart for the segregation of lepers is receiving the attention of the Government. The Protectorate is free from malaria, but this is, unfortunately, not the case with tuberculous diseases, which are increasing. This increase is accounted for by the habits of the natives, and the practice, as elsewhere in the Pacific, of overclothing themselves with European clothing, which when wet through, is allowed to dry on the body and

is at night time or when the heat is felt frequently discarded. Epidemics are of comparatively rare occurrence. The provision made for sanitation so far has been inadequate, and the low-lying nature of most of the islands of the group renders the matter of drainage a difficult one. During eight months (April-December) of the year the climate is good for a tropical one. The remaining four months comprise what is known as the hurricane season, in which the weather is hot and humid with a good deal of rain. The climate is not suitable for Europeans to perform hard manual labour in for any length of time. There is a hospital established at each of the three head centres in the group. Each is under a resident European medical officer. The benefits to be derived from these establishments are unfortunately not fully availed of by the Tongans. The latent faith in native pharmacy causes modern remedies and methods to be treated, as far as possible, with doubt if not with contempt. The civilisation of Tonga will have to be much deeper than it is before the natives can properly appreciate modern medical science and the services of its votaries. The senior medical officer at Tonga is Dr. C. E. Maguire.

E. D. C.—Such a circular note of professional qualifications and attainments should not, of course, be distributed to lay people in any broadcast fashion. Probably our correspondent would not have heard anything of the matter if his critic had known that only 10 or 12 patients had received the circular.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1910:—

Oct. 16th-22nd (Barcelona).—First International Spanish Congress of Tuberculosis.
Nov. 7th-12th (Cape Town).—Twelfth South African Medical Congress (1910).

In 1911:—
May-October (Dresden).—International Hygiene Exhibition.
June and July (Romford).—Town Planning and Modern House and Cottage Exhibition.
July (Birmingham).—British Medical Association.
August or September (Berlin).—Third International Laryngo-Rhinological Congress.
September (Brussels).—Exhibition of Fractures.
September (Sydney).—Australian Medical Congress.
Sept. 24th-30th (Rome).—International Congress on Tuberculosis.
" 25th-29th (Rome) Seventh International Congress of Dermatology and Syphilology.
October (Cologne).—International Congress of Criminal Anthropology.

In 1912:—
September (Washington, D.C.).—Fifteenth International Congress of Hygiene and Demography.

In 1913 the only fixture so far is in London, where the Seventeenth International Congress of Medicine will take place.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—H. Charles Cameron, H. H. Dale): at 4.30 P.M.

Presidential Address:
Professor A. R. Cushny, F.R.S.: A Plea for the Study of Therapeutics.

PATHOLOGICAL SECTION (Hon. Secretaries—C. Bolton, J. C. G. Ledingham): at 8.30 P.M.

Presidential Address:
Dr. F. W. Mott, F.R.S.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—H. G. Adamson, J. H. Sequeira) at 11, Chandos-street, W.: at 5 P.M.

Cases:
Mr. J. E. R. McDonagh: Cases of Syphilis treated by "606."
Dr. A. Winkelried Williams: (1) Gonorrhœal Keratosis of Palms and Soles; (2) Ulcerating Scleroderma improving under Mercurial Inunction; (3) Epithelioma of Chin, Simulating Actinomycosis.
Dr. H. G. Adamson: Atrophia Maculosa Cutis.

FRIDAY.

OTOLOGICAL SECTION (Hon. Secretaries—H. J. Marriage, Sydney Scott) at 11, Chandos-street, W.: at 5 P.M.

Discussion:
On Syphilis in Relation to Otology (to be opened by Mr. Arthur Cheatle, President of the Section).

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—Reginald Morton, G. Harrison Orton): at 8.30 P.M.

Paper:
Dr. Franz Nagelschmidt: The Thermic Effects produced by High Frequency Currents, and the Therapeutical Uses of Diathermic Treatment.

ROYAL MICROSCOPICAL SOCIETY, Doré Gallery, 35, New Bond-street, W.

WEDNESDAY.—8 P.M., The President will read a paper by Mr. J. J. Simpson: Hicksonella, a New Gorgonellid Genus.—Mr. E. M. Nelson: (1) Resolution of New Detail in a Coscinodiscus Asteromphalus; (2) A Micrometric Difficulty. Exhibition of Pond Life.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8 P.M., Card Specimens will be shown by Dr. C. Markus, Mr. G. W. Roll, and Mr. C. Blair. Mr. G. Coats will read a Paper.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Dr. A. G. Bagshawe: Recent Advances in our Knowledge of Sleeping Sickness.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY—4 P.M., Dr. H. B. Donkin: Harveian Oration.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

FRIDAY.—5 P.M., Prof. A. Keith: Specimens illustrating Obstruction of the Bowel caused by (1) Defects of the Diaphragm; (2) Peritoneal Pockets; (3) Imperfect Attachment of the Mesentery. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. C. Fox: Clinique (Skin). 5.15 P.M., Lecture:—Dr. G. Oliver: Some Bedside Clinical Methods (with demonstrations).
TUESDAY.—4 P.M., Dr. P. Stewart: Clinique (Medical). 5.15 P.M., Lecture:—Dr. E. C. Hort: Diagnosis and Treatment of Gastric and Duodenal Ulcer (continued).
WEDNESDAY.—4 P.M, Mr. D. C. L. Fitzwilliams: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. A. W. M. Robson: Certain Points in Diagnosis and Treatment arising out of his last 150 Operations for Duodenal Ulcer.
THURSDAY.—4 P.M., Mr. J. J. Clarke: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. F. H. Dally: Respiration in Health and Disease.
FRIDAY.—4 P.M., Dr. A. McNab: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Dunn: Glaucoma, its Varieties and Treatment.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Demonstration in Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. G. Stewart: The Diagnosis of Functional and Organic Disorders of the Nervous System (Lecture I.).
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. G. Stewart: The Diagnosis of Functional and Organic Disorders of the Nervous System. (Lecture II.).
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery (Lecture II.).
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin Disease.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.15 P.M., Special Lecture:—Mr. W. Turner: Some Surgical Conditions of the Large Intestine.
TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. Special Lecture:—2 15 P.M., Dr. G. Rankin: Endocarditis.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Buzzard: Myasthenia Gravis.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Buzzard: Myelitis.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Dr. Atkinson: Pharynx and Naso-Pharynx.

FRIDAY.—3.45 P.M., Lecture:—Dr. Abercrombie: Clinical Cases.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE CHEST, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Eczema, its Varieties, Symptoms, and Causes.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Habershon: Bronchiectasis.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. C. H. Melland: Some Conditions associated with Enlargement of the Lymphatic Glands. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (19th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (20th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (22nd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 6 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Harveian Oration

ON

SOME ASPECTS OF HEREDITY IN RELATION TO MIND.

Delivered before the Royal College of Physicians of London on Oct. 18th, 1910,

BY H. B. DONKIN, M.D. OXON., F.R.C.P. LOND., M.R.C.S. ENG.,

MEDICAL ADVISER TO THE PRISON COMMISSIONERS; DIRECTOR OF CONVICT PRISONS.

MR. PRESIDENT AND FELLOWS,—In offering the Harveian orator's solemn apology for accepting the honour conferred upon him I am personally conscious of discharging no vain formality. Having been long occupied in public duties but partly medical, and thus prevented from duly obeying the presidential biddings to the Comitia, I appreciated highly the compliment so graciously bestowed upon me by Sir Richard Douglas Powell in appointing me to this important office. The choice, however, of a fitting theme, and the difficulty, on an occasion like this, of handling that to which I inclined, caused me to hesitate gravely before taking up this honourable burden. Permit me now, Sir Thomas Barlow, while respectfully and cordially congratulating both yourself and the College on your succession to this famous chair, to plead for your merciful judgment on my present effort to fulfil your predecessor's behest.

HARVEY'S INJUNCTIONS IN REGARD TO THE ORATION.

The lapse of time since Harvey ordained this annual oration has rightly lessened the rigour of literal obedience to his injunctions. No oration in Latin has been heard for nearly half a century; nor has the annual feast been always celebrated within the College walls. In recent years, at least, no orator but Dr. Frederick Roberts has succeeded in the task of commemorating all our benefactors by name, this first Harveian injunction being usually fulfilled by the mention of such gifts made to the College, or such work achieved by its alumni during the past year, as may be deemed to increase its usefulness or redound to its glory. I cannot find that the year now passed has added to our benefactions of either kind. But there is one great name, besides that of Harvey whom we delight to honour unceasingly, that calls for signal note to-day. I am reminded that on the 6th of this month, 400 years ago, was born John Caius, nine times President of this College, virtual founder of the Cambridge college that popularly bears his name alone, and the second of the three illustrious ones on our roll to whom we can apply, in changing one word, the Lucretian saying, "Quasi cursores *medicinæ* lampada tradunt." Our own scholar-physician, Dr. Payne, whose frequent presence here is so sorely missed, has left in the minds of all who heard or read his Harveian Oration a vivid picture of Dr. Caius, stretching out one hand to our Founder, the famous medical humanist of the fifteenth century, the other to our immortal scientific physiologist of the seventeenth.

Though Caius, who taught Greek in Padua, and, later, essayed to prove that the University of Cambridge was founded in the fourth century before the Christian Era, may, in some respects, have been more nearly related in spirit to Linacre than to Harvey, yet his introduction of practical anatomy into this country, his work on "Some Rare Plants and Animals," and especially his admirable study of the sweating sickness, to which Payne refers as "the first original contribution to clinical medicine of which this country can boast," all, surely, tend to show that he had a true bent towards independent investigation, that his face was well set forwards, and that he sighted the beams of the rising sun of modern method. Let us, then, praise this famous man to-day as the first scientific physician on our roll.

I think that due reflection on the actual words and import of the historic document, wherein Harvey, among other express commands, enjoins the delivery of this oration, will justify some further adaptation of his orders in my endeavour to fulfil the spirit of his intentions. Harvey's motives were determined by the conditions of his time. Very prominent in this deed of gift is his intense desire to promote concord among the College members. The deed virtually begins and ends with insistent and particular warnings against discord, delicately though these warnings are expressed in terms of earnest call to professional harmony. Even the time-honoured order "to exhort the Fellows to search and study out the secrets of nature by way of experiment," brief as it is in comparison with his other and more emphatic injunctions, seems to echo his regret for the prevalent dogmatism and intellectual apathy of the physicians of his day. Doubtless Harvey enjoyed the high appreciation of many colleagues to whom he imparted his great discovery before giving it to the world. He was President-elect of this College. But it may be suggested, in view of his manifest superiority of intellectual grasp, that his commands were largely inspired by his sense of the defects of his medical contemporaries. Medical England was not ready for Harvey, albeit the spirit of science was abroad in the land, richly informing other branches of knowledge. This College, until long after his time, achieved little to foster even such a quest after a scientific basis for medical art as had been followed with insight by the great Greeks of old. Instead of encouraging scientific work by various honours and awards, as it does in our day, or of paying reverent tribute to scientific genius, as it did on that ever-memorable occasion when some of us were enabled at least to say *Darwin vidi tantum*, or of using its high privilege as a scientific body, by opening its doors as it did this year, to the defenders of research, it seems to have been busier in coercing the apothecaries, and in warning away from London the medical graduates of Oxford and Cambridge. But Harvey was in love with science; like Huxley, the great modern prophet of scientific method, he was penetrated by the missionary spirit, and eager to turn away his fellows from personal quarrellings and verbal disputations, he directed them towards the fruitful acquirement of medical truth by bidding them to the scientific study of nature for their better enlightenment.

If this view find favour, I may be pardoned for passing over what appears to me, in its literal sense, the most important of Harvey's exhortations, and for modifying adaptively that other special injunction to which, in common with my predecessors in this office, I strive to make response. If Harvey were with us now he would acknowledge that his dominant exhortation is needed no more; for he would note the extinction of rancorous disputes on medical superstitions and the rarity of overt personal jealousies, and would congratulate the physicians of to-day that only gross treason to medical truth and dishonourable conduct are likely to strain those fraternal bonds of science and a common profession which now so generally unite them. He would recognise also that the "way of experiment," even in the strict and modern sense of artificially designing conditions for the purpose of discovery, is now very widely followed, and would even justify the contention that this way of experiment, regarded exclusively as the only way to the attainment of sound knowledge, may sometimes lead to error instead of truth.

SCIENTIFIC METHOD.

It is solely in view of the biological nature of my subject, which, briefly, is that of Some Aspects of Heredity in Relation to Mind, that I venture to say here a few more words on scientific method. Outside the field of biology, or even of that section of it which is concerned with heredity, I might be charged with serving up a *crambe repetita*. But there seems to be a difference of opinion among biologists concerning the function and scope of experiment in the solution of scientific problems, some of them apparently holding, in view of the paramount necessity in some branches of science of the use of experiment in the ascertainment of facts or in the testing of hypotheses, that facts arrived at by observation alone are of minor value or comparatively negligible. At any rate, the well-known and accredited method of investigation which has been followed by Newton, Harvey, Darwin, and all great discoverers whose work is of permanent value, is not always employed. I mean, of course, the method (1) of observation (including the artificial variety called experiment), (2) of comparison and classification, leading to inferences or hypotheses or inductions, (3) of deduction, or prediction of the consequences which must follow on the assumption of such hypotheses, and (4) of verification, by the widest possible

appeal to all attainable and relevant facts, whether ascertained by observation or experiment, in order to see whether such consequences do or do not occur. The position that this—the method of "trained and organised common-sense"—is the method of all sciences of which the final aim is the discovery of causes, or interpretation, is perhaps not openly assailed; but there are some instances in biological writings where special value is apparently attributed to a fact because it has been found out by experiment rather than by simple observation; and also some instances of omission to test by deduction, and by a wide appeal to further relevant facts, hypotheses which have been based on experimental discovery alone. It is, of course, true that in sciences where, as in physics and chemistry, many of the facts are, in their nature, latent and obscured, the method of observation by way of experiment is indispensable for their discovery. So also is it indispensable over a large area of the field of physiology. But many facts in biology and medicine are patent to observation alone. Harvey, as a great physiologist, saw vividly the paramount importance of experimental work, both in ascertaining his facts and in deductively testing his conclusions; but surely neither he nor any other clear thinker would deny that when, in any field of study, such as that of the human being, normal and morbid, many patent and important facts present themselves clearly to direct observation, an injunction to proceed by the way of experiment only would prove to be a harmful limitation, and especially inimical to biological and medical inquiry. This subject of method is dealt with very luminously by Dr. Archdall Reid in his recent and attractive work on the "Laws of Heredity"—a book full of valuable thoughts and observations, which must tend to clarify greatly the reflections of many on the difficult problems of heredity, and especially those which relate to mankind.

In the present context this author says, "An hypothesis merely founded on facts, previously obscured, which have been revealed by experiment, has no special claim to accuracy. The subsequent thinking may or may not be accurate. To discover the accuracy of the thinking we have to use tests which that particular experiment, of course, cannot furnish. A neglect to *test* thinking founded on experiment, combined with an assumption that such thinking is necessarily accurate, is very frequent." This contention that a deductive test of conclusions arrived at by induction is necessary to establish proof, self-evident though it appears, has been stigmatised by some modern writers on biology as "merely deductive," "logical," "philosophical," "pre-Baconian," or even as mere "ratiocination," this last Latinised epithet being apparently preferred by the critic to the simple word "reasoning," for the sake of avoiding open discomfiture.

Such writers may well be referred to these words of De Morgan: "Modern discoveries have not been made by large collections of facts with subsequent discussion, separation, and resulting deduction of a truth thus rendered perceptible. A few facts have suggested an *hypothesis*, which means a *supposition* proper to explain them. The necessary results of this supposition are worked out, and then, and not till then, other facts are examined to see if these ulterior results are found in nature. The trial of the hypothesis is the *special object*, prior to which the hypothesis must have been started, not by rule, but by that sagacity of which no description can be given, precisely because the very owners of it do not act under laws perceptible to themselves. Wrong hypotheses, rightly worked from, have produced more useful results than unguided observation. But this is not the Baconian plan ..... What are large collections of facts for? To make theories *from*, says Bacon; to try ready-made theories *by*, says the history of discovery."[1]

I trust, therefore, that these few remarks prompted by my subject, which is concerned more largely with observation and reasoning than with actual experiment in the modern sense, will serve to excuse the version of the statutory exhortation which I now venture to deliver, in the form of a reminder, to all searchers of nature: To study out her secrets in every field, not by following any exclusive way, but by the use of that comprehensive method, common to interpretative sciences, which takes account of all authentic and relevant facts, and tests all thinking—the method, indeed, that was followed so notably by Harvey himself.

[1] See De Morgan's Budget of Paradoxes, pp. 55-56, quoted in Welton's Manual of Logic, vol. ii., p. 60.

My occupation of late years, much concerned as it has been with such matters as crime, inebriety, and mental defect, has directed my attention afresh to the subject of the evolution and inheritance of mental characters—a subject which attracted me, when, in the course of somewhat erratic reading for the Oxford Classical School, I perused the Origin of Species, then "mewing its mighty youth," and also the first edition of "The Physiology and Pathology of Mind," by our now renowned Fellow, Dr. Maudsley. As a further excuse for my choice of matter I may claim, as an encouraging precedent, the recent Harveian Oration by Dr. Ormerod, in which he showed, by quotations from the "Exercitationes de Generatione," that Harvey's mind had certainly dwelt on the subject of heredity in some of its aspects. And I hope before I close to show, from my own study of this great work on "Generation," that Harvey had at least a glimpse, among other cognate questions, of the want of some useful distinction between so-called "innate" and "acquired" characters—a want which, indeed, furnishes the point of many of the remarks I shall now submit. These are chiefly intended to emphasise the immense importance to man's life and progress of the characters called "acquired"—an importance, in my judgment, greatly underrated by some modern biologists.

EVOLUTION OF MIND.

I must first assume, with but brief comment, the position that mind has been evolved. Only on this assumption is it possible to inquire scientifically into the question of the inheritance of mental characters, and to seek for even a proximate explanation of their development and defect. I know, indeed, of but one living evolutionist of great and rightful fame, the co-discoverer with Darwin of the Law of Natural Selection, who, Darwinian or even ultra-Darwinian though he is on other points, explicitly holds that the origin of the mind and of sensation or consciousness in all organisms is, equally with that of life itself, outside the field of natural operations, and necessitates the assumption of a new power of spiritual essence.[2]

However true it may be, such a belief can be neither disproved nor contested by scientific reasoning. But while some relegate wholly such questions as these, with that of the primal origin of the universe, to the sphere of supernature, others feel compelled to seek for natural laws in any direction where scientific method may possibly guide them. For these the study of man, as we find him, practically presupposes that the development of his mind, with all its capacities, has depended on that of his mighty brain, which has been organically evolved under the influence of natural selection. Darwin himself taught the grammar of the evolution of mind, tracing it upwards from instincts to reason, from lower to higher organisms. Thus he laid the foundation for further scientific inquiry into the questions of the development and transmission of mental characters.

In making this assumption regarding the evolution of mind I assume, too, without argument, and for brevity's sake, the Darwinian doctrine which implies that the variations on which natural selection mainly works in the evolutionary process are germinal or innate, and are not caused by the action of the environment. Darwin, himself, in the chapter on the "Conditions of Life" in his book on "Variations[3] of Animals and Plants, &c.," after discussing the different possible causes of variation, sums up as follows: "We may conclude that the constitution of the individual is of far higher importance than the conditions to which it has been exposed. It is a general rule that conspicuous variations occur rarely, and in one individual alone out of millions. As the most strongly marked variations graduate insensibly into the most trifling, we are led by the same train of thought to attribute such slight variations much more to innate differences of constitution, however caused, than to the definite action of the surrounding conditions." And lastly, I shall assume the accordant doctrine, which is now held generally by most biologists, though apparently ignored by some and explicitly rejected by a few, that characters, commonly called "acquired," which depend on somatic modifications caused in the individual after birth, or, as some express it, are developed in the parents only under the influence of use and experience, are not developed in descendents in the absence

[2] See Wallace's Darwinism, pp. 461 et seq.

[3] See chapter xxii. of this work.

of similar influences, although the potentiality of such development is organically inherent in the innately variable germ-plasm.

I need hardly say that it is not my intention to attempt a discussion of the doctrines that conflict with these assumptions. Believing, however, (1) that the part played by non-transmissible acquirements has been, and is, of paramount importance to the progress of man in his never-ending attempts to make conquest of natural forces, or to destroy the effects of his own mistakes; (2) that the present biological evolution of man is to a predominant extent limited to a struggle against disease; (3) that there is no evidence to show that human mental capacity on the whole has materially increased within, at least, historical times; and (4) that the theory of natural selection according to Darwin, supplemented, as I have indicated, by that of Weismann, is the best explanation available of the development and inheritance of cerebro-mental functions, I cannot avoid certain incidental references to the teaching and methods of some who hold widely different views. And here I desire it to be understood, once for all, that in my incidental references to Mendelian views I am not calling in question such facts as have been established by this school of workers. I protest here mainly against the Mendelian hypothesis of "unit-segregation" being termed a "discovery," and employed as a fact in argument.

NECESSITY OF CLEAR CONCEPTIONS AS TO HEREDITY AND DEFINITE USE OF TERMS, ILLUSTRATED BY THREE TOPICS.

The topics of "criminology," mental defect, and "eugenics" may serve to illustrate the necessity of clear conceptions and a definite use of terms when we speak of the difference between "innate" and "acquired" characters. The *first* topic, that of so-called "criminology," demands, for the purpose in view, but a brief notice. Law-breaking, or criminality, is no unity. There are no special qualities, physical or mental, common to all criminals. The only important link between the study of crime and that of heredity is the fact that a considerably larger minority of persons with clearly appreciable mental defect, apparently of congenital nature, is found among convicted criminals than in the population at large. The notable number of mentally defective persons among criminals who are sentenced to penal servitude, and are usually the perpetrators of serious crime, impressed me at the outset of my prison work. Though it is difficult, and often impossible, to obtain an adequate history of the early life of these men, it is practicable, from inquiry and from study of the men themselves, to assert with much confidence that a significant proportion of them are of primarily defective mental capacity, or, as the old legal phrase has it, are "a nativitate mente capti." This conclusion is arrived at, independently of their criminality, from positive indications of mental defect observed in their conduct, and, in some cases, from certain concomitant physical characters. This class of mental defectives includes criminals of many kinds. They are, it seems, innately unable to acquire the complex characters which are essential to the average man, and, according to their surroundings, they follow the path of least resistance. This path is more often than not, but by no means always, the path of unsocial or criminal action. These statements about criminals will appear to be dogmatic, but are, I think, capable of proof. I have reason for believing that the report of an extensive inquiry now nearing completion, which has been carried out by the medical officers of our convict prisons, will go far, in itself, towards their justification. This matter, indeed, is of importance, not because any serious students of this subject now accept the doctrine of hereditary criminality or consider the so-called science of "criminology" as aught else than a mass of imperfect and unclassified observations linked together by untested hypothesis, but because this doctrine, so much emphasised by Lombroso, Max Nordau, and others, of the hereditary nature of crime, or, in other words, of the criminal being a racial "degenerate," is still very dominant over the public mind. It is widely popularised at the risk of producing practical effects, not only by writers of fiction, but also by philanthropists, journalists, and public speakers on social questions. It is apparently assumed as true by at least one prominent writer on biology;[4] while another disciple of Mendel proclaims that an "anarchist" is a germinal "mutation," which will breed true like other "sports." As all know, there is in this context much loose talk about so-called "degeneracy." This word "degeneracy" is mostly used without regard to its only legitimate meaning, which, of course, denotes *racial* change; and abounds in many works which are popularly mistaken for scientific studies. It follows from these remarks that it is unnecessary to discuss any question of relation between this doctrine and the scientific problems of the evolution and inheritance of mental characters, for no really rational hypothesis of hereditary criminality has been even formulated.

CAUSATION OF CONGENITAL MENTAL DEFECT.

My *second* illustrative topic is that of the causation of such mental defect as is usually called "congenital." The evidence concerning this matter, which was abundantly tendered by medical and other witnesses to the Royal Commission on the Control of the Feeble-minded, of which I was a member, evinced a frequent confusion or absence of thought on the meaning and right use of the word "heredity." This evidence, some of it being of great value, was accepted, after some discussion, by the Commissioners, although the question of causation had not been explicitly referred to them. It was therefore dealt with to some extent in the report, although the constitution of this commission, in common with that of some others on cognate subjects, was not adapted to deal exhaustively with questions involving scientific, and especially biological, problems in relation to human beings. Some of the witnesses held that the forms of mental defect under consideration were largely inherited, while at the same time they attributed their occurrence in offspring to quite different characters in the parent, such as alcoholism, tuberculosis, malnutrition, or other disorders incident on slum conditions or unhealthy surroundings generally. Others considered all cases of mental defect as "hereditary" when there was any history of insanity or "nervous disorder" of almost any kind among the more or less immediate ancestors. Others, again, used the word "heredity" in the strict sense, and applied it only to characters which appear to be organically innate or "germinal," and are of like nature with ancestral traits. So apparent, indeed, even to the non-medical members of the Commission were the confusion of thought and the inaccurate language which pervaded much of the evidence on this head, that the report expressed the unanimous opinion that the important subject of heredity should be especially emphasised in the medical curriculum.

It is impossible to discuss here the complicated question of the causation of congenital mental defect. My main object in speaking of it is, as I have said, to illustrate the importance of forming clear conceptions concerning heredity, and of carefully defining the terms we use. It may be said, however, that although there are no adequate statistics showing the comparative numbers of such defectives engendered by normal and defective parents respectively, there is a wide consensus of opinion, based on much accurate observation, that a lineal sequence of defectives is sufficiently frequent to render it highly probable that this condition is in a large number of instances truly innate and thus transmissible, or, in other words, that it is thus dependent on a germinal variation of the brain. Those who accept, as most biologists ostensibly accept, the conclusion that characters developed by parents after birth in response to environmental influences are not transmitted to offspring as innate characters not requiring such influences for their development, must reject wholly the doctrine that bad nutrition, or other evil conditions or diseases contracted by the parents, can appear in the offspring in the form of such abnormalities of the brain as must subsist in all, as it is known to subsist in many, of the cases of mental defect we are now considering. They will hold, as a more likely hypothesis, that such mental defect, especially in the absence of any injury to the brain of the offspring during fœtal life or at birth, is, at least in most cases, a spontaneous variation, probably in the direction of some ancestral condition, and tending to be

[4] Professor Bateson, in his book on Mendel's Principles of Heredity, p. 306, writes as follows, after having stated on a previous page that in "the pre-Mendelian period, the expression 'genetic' had no definite meaning": "Genetic knowledge" (by which, it may fairly be presumed, is meant the doctrine of heredity according to the Mendelian hypothesis of unit-segregation) "must certainly lead to new conceptions of justice, and it is by no means impossible that in the light of such knowledge public opinion will welcome measures likely to do more for the extinction of the criminal and degenerate than has been accomplished by ages of penal enactment."

transmitted to descendants. Those, on the other hand, who attribute such mental defect to various modifications acquired by the parents during their lifetime must not only believe in a multiplicity of causes for a similar effect, but must also hold the view of the modification of the germ-plasm by environmental influences to such a wide extent as would involve the necessary inference of the rapid degeneration and ultimate destruction of the race as a whole. I cannot now pursue this interesting subject, and will but express my opinion that the conclusive answer to this particular question will probably not be given without a more extensive knowledge of facts than is at present available. From all that I have been able to gather from the best authorities on the physical characters of the brain of imbeciles, no absolutely positive statement can yet be made from the anatomical point of view as to how far true retrogression, or how far arrest of fœtal development, can be said to contribute towards the solution of this problem.

EUGENICS.

My *third* topic is that of "eugenics," a subject of present-day interest, both to scientific workers and to the public at large. The main object of human eugenics, according to Sir Francis Galton, the inventor of the term and the originator of the inquiry it embraces, is the discovery "of the amount of change in racial qualities which can reasonably be anticipated," and what can practically be done in the direction of effecting an improvement in such qualities "by selective breeding."[5] I shall refer here to the method of this research only as it concerns the question of the inheritance of *mental* characters. The method generally is to deal measurably and statistically with "faculties" or "characters" that are variously distributed in a large population. If, for instance, the proposition be true, that there is in any nation greater "fertility" of the mentally inferior than of the better and more able "stocks," and if it be assumed that the use of the word "stock" implies that the mental difference referred to is of innate or germinal origin, then it follows that the only remedy would be a possible alteration of the relative fertility of such stocks. Now, without raising here any question as to the definition of the word "fertility," it is apparent that any possible improvement of a stock depends on some assumption that the qualities under consideration are really innate and transmissible. However accurately the calculating apparatus may work in dealing statistically with the material collected for its operations, the practical value of the result attained must rest entirely on the nature of the items of material which are thus operated upon. And the important question then arises: Are such "characters" as, for instance, "ability" or "probity," really indications of "stock" qualities? Are they germinal and transmissible, or acquired? As to "ability," if this term were strictly defined in a certain way the answer might be that it is germinal; if defined in another way, that it is acquired. As to "probity," it seems to me, at least, plain that the reply must be that it is acquired.[6]

Touching the mental and moral characters of man, there is massive evidence which shows that many even of the most importantly adaptive among them are the result of "modifications," developed in each individual under the stimulus of actual use and training alone. Such characters are mainly and clearly traditional; they are handed down by each generation to the next through teaching and example, not through real inheritance; but their constant acquirement by every generation gives them the appearance of naturally inherited qualities. This question should cause all students to pause and consider seriously before they assume that any given character is not only inborn but has also been developed apart from such influences, or in other words, is not an "acquired" or "somatic" modification. These remarks appear to apply also to the utterances of many adherents of the Mendelian school of biologists, who, though widely differing from the biometrical school in respect of fundamental questions of evolution and heredity, seem, in common with their opponents, to consider acquired mental characters, or "modifications," as unimportant; and to class such qualities as they deem at all important with those which are "germinal" and require no external stimulus for their development other than such as is implied in life itself.

I must especially state here that I fully recognise the importance of possible attempts to improve the human race either by limiting or eliminating the bad, or by encouraging the good stock. We may, perhaps, have knowledge enough already to make some practical advance in what has been styled, and by some depreciated, as "negative" eugenics. But we must bring much more biological knowledge and very clear minds to bear upon the subject before attempting any measure in the direction of "positive" eugenics, and especially in that of "selective breeding" on the basis of what we regard as innate mental characters. In connexion with the desirability of limiting the production of mental defectives on the hypothesis—which, although not demonstrated, is regarded as highly probable by most observers—that mental defect is largely innate and transmissible, I would mention the following facts, taken from Dr. Ireland's book on "The Mental Affections of Children," as suggesting reflection on the question of making such a step in the direction of negative eugenics as that of trying to minimise the production of mental defectives. The average mortality, during a certain period, of imbeciles between the ages of 5 and 20 years in two large asylums was at least nine times as great as that of sound-minded young persons at the same period of life in corresponding years. Dr. Ireland adds that in an asylum well known to him, the substitution of a non-resident doctor for a resident medical superintendent was followed by a rise in the death-rate above double. His comment on this implies his opinion that the protection of the lives of imbeciles is an important function of medical art. From one point of view this opinion is right, but from another we are led to reflect how often Nature's method of negative eugenics is effectively antagonised by man. Though imbeciles in asylums are of course incidentally prevented, for the most part, from propagating, infinitely larger numbers of many grades are permitted to bear and beget children from sentiments very similar to those which tend to foster any measures for prolonging the life of all.

The necessity of some clear conceptions of the nature of "innate" and "acquired" characters, as well as of heredity and of the evolutionary process, is now abundantly evident, whether mental or bodily characters be the subject of study. Even though biologists may perhaps agree in the belief of the continuity and a high degree of inviolability of the germ-plasm, in the consequent non-transmissibility of acquired modifications, and in the doctrine of evolution by the action of natural selection on germinal variations alone, they certainly differ as to what characters should be classed as germinal variations or acquired modifications respectively; and such differences are manifestly important. They also notoriously differ as to whether the material for natural selection consists mainly of small and so-called fluctuating variations as necessarily implied in the theory of Darwin and Wallace; or only of "sports": "large," or "discontinuous," or "saltatory" variations, now commonly called "mutations," which are said to be stable from the first, and alone to be of "genetic" value in evolution. This latter hypothesis was long ago opposed to Darwin's theory by the late Mr. St. George Mivart, who held that new species manifest themselves with suddenness and by modifications appearing at once; and, in a more elaborate form, based on "some facts and a hypothesis," is promulgated by mutationists and some Mendelians of the present day, who more than hint that the Darwinian theory of natural selection is largely a superstition. Differing hypotheses are also upheld, by the followers of the Mendelian and Galtonian methods respectively, in connexion with the hereditary transmission of characters: the one school adopting that of the unit-segregation of characters in the germ-plasm, the other those which are known as the laws of "ancestral inheritance" and of "filial regression."

TRANSMISSION OF "EDUCABILITY."

I have said that I have no intention of discussing here the various opinions alluded to. I shall consider, only and briefly, that exposition of biological evolution and heredity in relation to man and his mind which seems to cover fitly

[5] See the "Herbert Spencer" lecture by Sir F. Galton, 1907, Clarendon Press, Oxford. See also "Natural Inheritance," 1889, "Huxley Lecture" (1901), and several papers by the same author in the "Memoirs of the Sociological Society"; also Professor Pearson's "Huxley Lecture" (1903) in vol. iii. of "Biometrika."

[6] I am aware that it may possibly be said that any statistical inquiry resulting in the inference that "probity is inherited" does not necessitate any special theory of heredity; but it seems clear that a definite conception of what the word "inherited" means is necessary in the practical context of this matter of selective breeding, which explicitly concerns the research in question.

the complex facts which present themselves and to be contradicted by none of them: I mean the theory of evolution as set forth by Darwin and by Wallace, and as supplemented by the doctrine of the non-transmissibility (to offspring) of acquired modifications—i.e., modifications developed in the parent after birth under the stimulus of use and experience alone. Darwin himself, as I have said already, taught the grammar of the evolution of mental and moral characters, basing his argument on the existence of the social instinct in man. He formulated, however, no positive theory of heredity, though he saw the need of one; and, assuming the probability of some characters acquired by parents being transmitted as such by immediate inheritance to their offspring, he suggested the hypothesis of pangenesis. In his "Descent of Man," nevertheless, he displays in more than one place some hesitation in accepting his own tentative opinion on this point. Writing of Spencer's hypothesis of the transmutation of experiences of utility, by a process of continued transmission and accumulation, into inherent faculties of moral intuition, he suggests that, if insanity and other morbid mental or moral tendencies connected with cerebral or other bodily states can be transmitted, it is probable that good tendencies are transmitted likewise. "Even the partial transmission of virtuous tendencies," he says, "would be an immense assistance to the primary impulse derived from those social instincts which are the true basis of moral evolution by selection." "Admitting," he says further, "for a moment that virtuous tendencies are inherited, it appears probable that they become first impressed on the mental organisation through habit, instruction, and example continued during several generations in the same family." But he adds, "My chief source of doubt with respect to any such inheritance is that customs, superstitions, and tastes, such as the horror of a Hindoo for 'unclean' food, ought, on the same principle, to be transmitted. I have not met with any evidence in support of the transmission of superstitions, customs, or senseless habits."

The doctrine of the leading biologists of the present day who recognise the truth of the principles of evolution as established by Darwin, and who hold, in substitution of Darwin's supposition of the transmissibility of some acquired characters, that it is "educability," or the organic capacity for making such acquirements, not the acquirements themselves, which is innate and transmitted, seems to form the only synthesis which covers the known facts of heredity, is contradicted by none, and tends, in consequence, to be of further interpretative value. The conclusion is evident, in the application of this doctrine to mental development, that "the mind of the human *adult* is mainly a social product, and can be understood only in relation to the special environment in which it develops, and with which it is in perpetual interaction." "The recognition of this truth," said Sir Ray Lankester in his Presidential Address to the British Association, "seems to be the most important advance in psychology in recent years."[7] It follows that the innate and transmissible factor of the mind of man is the organic potentiality for making mental acquirements, which, in man, has been highly evolved by natural selection. In this context I would make special reference to several pages which follow on the quotation from the address I have just mentioned. I can, however, quote now but one passage, which very closely bears on the relation of scientific psychology to the theory of the origin of structural characters by natural selection. "In discussing," says the author in a communication to the Société de Biologie of Paris in 1899, "the significance of the great increase in the size of the cerebral hemispheres in recent as compared with Eocene mammals, and in Man as compared with apes, I came to the conclusion that the power of building up appropriate cerebral mechanism in response to individual experience, or what may be called 'educability,' is the quality which characterises the larger cerebrum, and is that which has led to its selection, survival, and further increase in volume. The character which we describe as educability can be transmitted; it is a congenital character. But the results of education *cannot* be transmitted. In each generation they have to be acquired afresh. On the other hand, the nerve mechanisms of *instinct* are transmitted, and owe their inferiority as compared with the results of education to the very fact that they are not acquired by the individual in relation to his particular needs. To a large extent the two brain mechanisms, the instinctive and the 'individually acquired,' are in opposition to one another. The loss of instinct is what permits and necessitates the education of the receptive brain."

A very full and detailed exposition of this most important truth, with its numerous bearings, is given by Dr. Reid in the remarkable book to which I have already referred.[8] In that part of it which treats of the development of mind he maintains, by an array of evidence, that the great peculiarity of the human being as compared with other animals is that the most distinctive characters of his mind arise much less, as he expresses it, under the stimulus of nutriment alone, and much more under that of use and experience; that his instincts are fewer, while his capacity for making acquirements is infinitely greater and more variable; and that since "nature" has rendered man transcendently responsive to the "nurture" of use and experience, the question, so often asked, whether nature or nurture plays the most important part in the development of the human mind, has really but little meaning. "Capacity" or "ability" for making mental acquirements is innate and transmissible; it resides in various degrees in the immense brain of man; but for its development in special directions it requires the appropriate stimulus. The physical and mental maturity of the normal human being thus depends very largely on acquirements, the making of which is as essentially a part of adult development as is the growth of head and limbs of fœtal development. In terms of structure we may regard the innate mental characters as depending on cerebral mechanisms which are germinal, inherently active, and transmissible; and the acquired characters as depending on mechanisms developed after birth in the still organisable substance of the brain, but as developed only under the influence of the environment, as somatic modifications, not transmissible.

In a recent and practical text-book on "Mental Deficiency,"[9] the following expression of the difference in question is somewhat similar in effect to those which I have mentioned. "The development of mind," says the author, Dr. Tredgold, "takes place in consequence of two influences: spontaneously, or an inherent tendency of the brain-cells to develop, and stimulation of these cells by external impressions. The brain of the healthy child is capable of utilising and responding to any surroundings, within ordinary limits, in which it may be placed. The defective mind is lacking in this power. One of its chief characteristics is a want of what may be termed 'mental aggressiveness.'" It seems to me that the author here implies that what he terms "mental aggressiveness" is innate, and that the power of response to the environment is in direct proportion to the development of this quality.

If, then, it should be proved that imbecility is largely transmissible and innate, it may be thus far regarded as a possible reversion to an ancestral condition, though the reversion is, of course, not complete. Stated by Dr. Reid, in terms of mind, the defect of the imbecile is that he cannot learn; he lacks, or is greatly deficient in, the power of making mental acquirements; he is not able, as the normal individual is, to profit from experience; he has little or no memory, a mental quality depending on a late stage of cerebral evolution, and constituting the primary factor in the power of making mental acquirements. While he has lost the power of profiting by experience he has regained no part of the lost power of being guided by instinct. Therefore he is comparatively helpless as compared to the lower animal. But the instincts which normal beings possess, such as, for instance, the sexual, may appear unduly prominent in him, for he cannot learn to control them.

IMPORTANCE OF EDUCATION.

These general considerations on the subject of "innate" and "acquired" characters afford a good illustration of the different conclusions which may be arrived at on this and other matters, according to the different views held by inquirers concerning evolution and heredity, or to the different methods of investigation followed. Some biologists, holding certain principles of heredity, and basing their

[7] See Lankester's Kingdom of Man, p. 122 (Constable, 1907).

[8] The Laws of Heredity, by Archdall Reid, M.B., F.R.S.E. Methuen and Co., 1910.

[9] Mental Deficiency (Amentia), by Dr. Tredgold. London: Baillière, Tindall, and Cox. 1908.

inferences mainly on facts statistically arranged, appear to regard most moral and intellectual characters as instincts, and, as such, inherited. In common, apparently, with the otherwise widely differing school known as Mendelian, these regard the body and mind of an adult human being as consisting of innate and acquired characters, and hold that all the important mental characters are germinal and transmissible, and can therefore be made, by selective breeding, factors in true evolution. It is needless to dwell on the wide gulf which practically separates this view from that of those who believe that the innate mental characters of man, though of immense racial importance, and possessing great variability, are few in comparison with those which have been acquired and are demonstrably not transmitted; that most characters of the highest social importance are only traditionally handed down; and that even the achievement of civilisation by a savage race implies no necessity of germinal alteration. Reflection on these problems leads, I think, to the probable conclusion that man's mind, like his body, is certainly both born and made, but that his adult mind is much more made than born. The slow evolution of the brain and its functions through the natural selection of adaptive variations has produced the enormous inborn power of making mental acquirements that is now the organic heritage of man. Thus, among innumerable acquirements, he has gained the unique facility of recording his discoveries and thoughts by the instruments of speech and letters, and thus he has created a traditional wealth of knowledge—a veritable and priceless heritage of a wholly different kind "treasured up on purpose to a life beyond life."[10]

The manifest bearing of these truths on the principles of education indicates that the right object of education is to fit human beings for their social existence, to make them good citizens, and to afford those with gifts above the average the opportunity of developing them. Education modifies and greatly makes the individual, but it does not affect the biological evolution of the race. It has been strikingly written by an eminent Darwinian—Sir William Thiselton-Dyer—that, "there is no more pathetic feature in human experience than to see descend into the grave, to pass away for ever, all those endowments with which genius and labour have adorned individual human beings. The cunning hand of the artist, the entrancing skill of the musician, the song of the poet, the eloquence of the orator, all perish with their possessors, and 'leave not a wrack behind.' Were it otherwise the toil of education would have been mitigated, and there would have been no bounds to the mental acquirements of the race. But when our first parents tasted of the tree of knowledge, the tree of life was denied them, and knowledge perishes with its possessor."[11] It is perhaps from reflections such as these that some men eagerly welcome any biological teaching which tends to minimise the immense importance to man of his acquired character, or to justify in any degree the belief that such characters are naturally transmitted from parents to offspring. But Tennyson's words still ring true for us. Though "the individual withers, the world *is* more and more"; though nature seems "careless of the single life," she is very "careful of the type": and we may still join in the poet's youthful and stirring cheer to—

> "Men our brothers, men the workers, ever reaping something new;
> That which they have done but earnest of the things that they shall do."

Since man invented speech and letters the results of his acquirements have been immortalised. The age-long lessons and records of his thoughts and achievements have alone directed and still increasingly illuminate his onward march. But were it possible for these lights to fail, were all the knowledge and civilisation acquired by the human race to perish, "the mind's great age" would hardly "begin anew," for the race itself in the struggle for life would probably cease to be.

MENTAL ACQUIREMENTS NOT TRANSMITTED.

Small as is the knowledge we possess as yet of the beginning, limitations, qualities, and operations of the mind, there may be much for us to learn from further observation of various diseased states of the brain, as well as from continued use of the methods of experimental psychology and from the investigation of hypnotic phenomena, so ably advocated by Dr. Savage in last year's Harveian Oration. But we know a little more perhaps about the evolution and development of the body, including that of the brain. By those who incline to that view of heredity which seems to make the nearest approach to truth, the germinal factor in this organ will be regarded as the substratum and condition of all mental development, endlessly transmissible, infinitely variable, and richly endowed with capacity for making acquirements; but as standing, nevertheless, in absolute need of external influences in order to develop most of the distinctive and special characters which we recognise as intellectual and moral. With the germ-plasm, as a whole, in all its variability and liability to death and injury, the mind's organ is approximately inviolable to vital and transmissible change from the action of the environment, and no mental acquirements or modifications developed during an individual life-time are transmitted to descendants. The germ may die, but living it will not surrender its essential qualities to the action of external forces. The spontaneous variability of the germ appears to be a basal conception, necessary at present to all evolutionists, for the origin of so-called "genetic mutations" is confessedly as mysterious and "spontaneous" as that of the fluctuating variations, among which, according to the theory of Darwin, natural selection mainly works in the production of fixed species. The origin of mutations, indeed, would seem to be the more mysterious, since these are said to be "genetic" or fixed from the start, and thus might as well be described as "special creations." Further, the belief in the great resistance of the germ-plasm to transmissible organic change from external action seems to be necessary for any explanation of heredity whatever. The cause of normal hereditary transmission is surely at least as mysterious as that of any variations, small or great, fluctuating or discontinuous, unless the well-nigh demonstrable doctrine of the continuity and approximate inviolability of the germ-plasm be fully accepted. Without the aid of this pregnant hypothesis all biologists must confess that the simple but weighty question asked by Harvey, "How does like ever generate like?" is still wholly unanswered.

OBSERVATIONS OF HARVEY ON HEREDITY.

That some of the problems I have glanced at were even vividly present to Harvey's mind appears from the following quotation from Willis's translation of the work on Generation. The question of hereditary transmission and of reversion to ancestral types is raised when he writes: "In reference to the subject of family likeness we may be permitted to inquire as to the reason why the offspring should at one time bear a strong resemblance to the father, at another to the mother, and at a third to progenitors, both paternal and maternal, further removed, particularly in cases where at one bout and at the same moment several ova are fecundated. And this, too, is a remarkable fact that virtues and vices, marks and moles, and even particular disposition to disease, are transmitted by parents to their offspring, and that while *some inherit in this way all do not.* Numerous qualities, in fact, both of mind and body, are derived by hereditary descent." Again, he says: "I have frequently wondered how it should happen that the offspring, mixed in so many particulars of its structure or constitution, with the stamp of both parents so obviously upon it in so many parts, should still escape all mixture in the organs of generation; that it should so uniformly prove either male or female, so very rarely an hermaphrodite." Here the modern problem of the alternative development of certain characters is apparently suggested.

In the Exercise "Of the Order of the Parts According to Aristotle," and in a context which need not be specified here, Harvey quotes some of Aristotle's words as follows: "..... *as then man's growth being complete and mind having been superadded* .....," and he adds: "In other words (and as I interpret the passage), adult man having acquired sense and prudence." Is there not an inkling here of the great question regarding "inherited" and "acquired" characters? Again, in the next Exercise, Harvey writes: "The proportion of the body to the extremities in children after their birth continues excessive until they begin to stand and run." May he not imply here the

[11] See Edinburgh Review for October, 1902—Article on "Darwinism."

necessity of use in the development of certain physical characters which otherwise would not appear? And, further on, he says: "Man comes into the world naked and unarmed, as if Nature had destined him for a social creature and ordained him to live under equitable laws and in peace, as if she had desired that he should be guided by reason rather than be driven by force; therefore did she endow him with understanding and furnish him with hands that he might himself contrive what was necessary to his clothing and protection."

Once more Harvey profoundly reflects: "The vegetative faculty of parents engenders in conformity with determinate laws in the same way as light things rise and heavy things descend, and the semen arrives at the form of the fœtus as the spider weaves her web, as birds build nests, or as bees and ants construct dwellings and lay up stores for future wants, all of which is done naturally and from a connate genius or disposition, by no means from forecast, instruction, or reason. That which in us is the principle or cause of artificial operations and is called art, intellect, or foresight in the natural operations of lower animals is nature, which is αὐτοδίδακτος, instilled by no one: what in them is innate or connate is with us acquired." Here Harvey's thought verily seems to have been searching for some distinction between the nature and mode of development of innate and acquired characters, and dwelling on the immense importance to man of what we have regarded as his acquirements, the mechanism of which he cannot transmit to his offspring.

MAN MUST "CULTIVATE HIS GARDEN."

We may hold, then, that by the achievements of his mighty brain, with its inborn "educability," "memory," or ability to make acquirements in response to his environment, man has entered into his kingdom. This ability, of infinite variety though it is in different individuals, is normally immense, and its organic mechanism marks man's brain alone. At birth the individual mind is equipped in full measure with that capacity of development which is its lot. This capacity is shown at its highest power in early life, though its activity endures for years. But the direction such development takes depends mainly or wholly upon influences or stimuli from the external world, and what we recognise and speak of as the intellectual and moral faculties are the immediate products of external influences which actuate the potencies of each individual brain. We may fancifully figure man's mind at birth as a many-chambered mansion of noble plan and wondrous structure, awaiting the majority of its owner for its full utility and final adornment. More justly, perhaps, for the purpose of illustrating these reflections, we may liken it to a garden endowed with bountiful soil, the produce of which depends on the quality and the nurture of the plants grown within it. And the lesson is, man must still "cultivate his garden" and cultivate it aright. Should he neglect it, and should he not then inevitably perish (for it is his only resource), it would revert to its earlier and wilder condition under the cessation of selection, and the forces of circumambient Nature. In his book—the "Kingdom of Man"—from which I have already quoted, Sir Ray Lankester says: "Civilised man is a successful rebel against Nature, who by every step forward renders himself liable to greater penalties. His only hope is to control the sources of these dangers." Now if it be admitted, as Dr. Reid has so fully shown, that man's evolution to-day is mainly against disease and other destructive agencies, that there is no evidence in favour of any marked germinal improvement, within at least historic or even much earlier times, of man's mental capacity, and that his enormously increased and increasing powers of adapting himself to Nature and of controlling her forces, or, in other words, his advancing civilisation, are mainly the products of his acquirements, it follows that in all our attempts to promote "eugenics," and still more (because the object is immediately practicable) to improve the education of our youth so as to adapt them to the inexorable exigencies of their time, we must duly recognise that the progress and the efficiency of man, whether destined to be permanent or not, are by no means questions of breeding alone. "Education," says Huxley, "is the instruction of the intellect in the laws of Nature, under which name I include, not merely things and their forces, but men and their ways, and the fashioning of the affections and the will into an earnest desire to move in harmony with those laws." There is truth, too, in Huxley's saying "that the stupidity," and I might add, the superstitions, observable among the so-called "educated" classes of to-day "is largely caused by the repressive action on natural intellectual appetites of a Procrustean system of artificial teaching." In these classes especially abound the Christian Scientists, telepathists, and other spiritualists of many colours, as well as anti-vivisectionists, anti-vaccinationists, and divers other persons whose only bond of union seems to be impatience or hatred of the scientific method of thought. One high duty, at least, of men whose life-work is to "search out the secrets of Nature" appears to be plain: To strive for the reform of education according to the dictates of science—*Hic labor, hoc opus est.* Even though all aims at the artificial improvement of the human germ be disappointed, we can truly and fruitfully educate our race by insisting on a thorough and enlightened study of Nature and her laws. We know at least that the unity of the universe is a scientific fact. "We are governed by physical laws which it is our duty, as scholars of Nature, to investigate; and by moral laws which it is our duty, as citizens of Nature, to obey."[12]

We are not without object-lessons of what intelligently directed education can achieve for a whole people even in one generation. To no germinal change can possibly be ascribed the recent development and marvellous transfiguration of Japan. Doubtless, indeed, we may sing with the matchless poet of humanity who was Harvey's contemporary, "What a piece of work is Man, how noble in reason, how infinite in faculty! In form and moving, how express and admirable; in apprehension how like a god!" But we can also endorse his further reflection:—

> "Sure He that made us with such large discourse,
> Looking before and after, gave us not
> That capability and god-like reason
> To fust in us unused."

Remarks
ON
THE ROYAL NAVY MEDICAL SERVICE.

Delivered at the Distribution of Prizes to Naval Medical Officers at Haslar Hospital on Oct. 7th, 1910,

BY ADMIRAL SIR JOHN DURNFORD, K.C.B.

GENTLEMEN,—I understand that on this occasion I am expected to say a few words, and in the first place, on behalf of those who have been good enough to attend this prize distribution and in my own name, let me offer our congratulations to the medical officers who have now successfully qualified for commissions in His Majesty's Navy. I can assure them of the high esteem in which the Naval Medical branch is held by the whole Service and also by those who control it. You have at a considerable pecuniary outlay selected a profession of great importance, and a responsibility devolves on you which is not surpassed and rarely equalled in any other calling. You will have to depend mainly on your own judgment and skill, to act promptly, generally without anyone to consult as to the steps to be taken. So far you are circumstanced as many of your professional brethren who practise on shore. But you, gentlemen, have undertaken a further responsibility, that of accepting a definite share in the defence of the Empire by joining His Majesty's Navy, a profession which is rightly and justly esteemed of incalculable importance, as the safety of the Empire depends on the strength and efficiency of its fleet. It should be your aim throughout your career, by careful study, research, and practice, to keep abreast of the times in your profession, and to maintain the *personnel* of the fleet in the highest state of physical fitness reasonably possible. You should remember that the prospect of ultimate success will be much greater if the occasional somewhat monotonous periods that occur during peace are spent in preparation for the supreme moment.

I have during my experience found the advice of the

[12] See Winwood Reade's Martyrdom of Man, p. 180.

medical officer of great value in the conduct of the Service. I have always considered him one of my most trusted advisers, and this confidence has never been misplaced. It is desirable that you should pay much attention to the training and advancement of the sick-berth staff on whom much depends. Encourage their attention to the sick, their industry and laudable ambition.

In the presence of so much medical and surgical talent who can better tell you, I find it difficult to offer you professional advice, and would therefore merely say that if you have a special leaning for medicine or for surgery, or any particular branch of either, by all means cultivate it, provided you can do so without interference with your excelling as a general practitioner. This proviso is necessary, for though we welcome a limited number of expert specialists, who devote their whole time to some particular branch, the bulk of the naval medical officers should be constantly working at all available subjects, both in medicine and surgery, as they have cases of all descriptions to deal with, and must be independent of outside expert assistance.

A matter of deep interest to the Naval Medical and Nursing Services, and one of very considerable importance to the nation, is the question of the provision and organisation of these services in peace and also in war, and whether any steps are considered necessary to render them more efficient. In short, whether we are reasonably and satisfactorily ready for emergencies. These questions have been carefully considered by a committee with which I have been connected. Our discussions extended over nine months. Besides sub-committee meetings to elaborate details, we held some 60 sittings and produced a unanimous report. I am glad of this opportunity to say how greatly our deliberations were assisted by officers of the Services and eminent members of the civil medical profession, who in response to requests gave us the benefit of their opinions, the outcome of long and valuable experience. It is not only the oral evidence I allude to, but also the carefully prepared papers and numerous letters received in reply to inquiries.

I should also like to mention the valuable advice afforded by the matron-in-chief of the Army Nursing Service, the senior head sister of the Naval Nursing Service, as well as similar authorities of the highest standing in civil life. Their assistance was of great value in considering H M. Queen Alexandra's Royal Naval Nursing Service, a service of such highly proved use in peace, and one on which a still greater reliance must be placed in war. The help and assistance from the St. John Ambulance authority were also most useful, and I must not forget to include also the Royal Naval Volunteer Reserve. The prompt and ready response from the home hospital authorities in the matter of furnishing information and statistics was of much assistance, and I am glad to express our thanks to the inspectors-general and officers of the hospitals for their share in this matter. Beyond the allusions made in Parliament by the First Lord of the Admiralty, it has not yet been possible to make public the recommendations which have been made, and you will not therefore expect me to go into them. I have good reason to hope, however, that having now been considered by the Admiralty, effect will be given to the committee's recommendations as soon as arrangements can be made.

May I say that though undoubtedly you will find some difficulties in a naval career, there is much to recommend it. You cannot fail to appreciate the associations, your work, and the opportunities and advantages incidental to a life of travel. You may not obtain the reward a Harley-street reputation sometimes carries with it, but if you persevere you will obtain the most satisfactory recognition a naval officer can aspire to: I mean the good opinion of the great silent sea service which, when merit is deserved, communicates its appreciation in no uncertain voice. This and the gratitude of the officers and men you serve, and sailors are not ungrateful, will, I trust, stimulate your zeal in what I hope you will find a satisfactory career.

In conclusion, I desire to express sincere thanks for the kind welcome you have given me. It is always a pleasure to visit this establishment, in which I have taken so great an interest, and I particularly appreciate the opportunity the Director-General and your Inspector-General have afforded me to meet old friends. I am confident Haslar will continue to maintain its high position in the future. You will all, I am sure, join with me in thanking the Commander-in-Chief and Lady Curzon-Howe for their kind attendance here this afternoon; their presence greatly enhances the situation, and is another proof of the kindly and affectionate interest in the *personnel* of the Service which they have always displayed throughout my old friend's distinguished and conspicuous career.

Abstracts
OF
INTRODUCTORY ADDRESSES, ETC.,
DELIVERED AT THE
Opening of the Medical Session 1910–11.

LONDON SCHOOL OF TROPICAL MEDICINE.

INTRODUCTORY ADDRESS ON "SCIENTIFIC OBSERVATION," DELIVERED BY H. A. MIERS, D.SC., F.R.S., PRINCIPAL OF THE UNIVERSITY OF LONDON.

Dr. MIERS, speaking as Principal of the University of London and disclaiming any personal knowledge of tropical medicine, began by pointing out that the coöperation of workers in different subjects, whether by advancing criticism or by direct collaboration, should be one of the most valuable and effective features in a university, and he considered that those working in their professions might more consistently and systematically take their problems to the universities for solution as places where there is, or should be, time and opportunity to carry out researches of which the practical outcome might not be at first evident. He instanced the microscopic study of rocks and metals, which has revolutionised geology and metallurgy, as studies which could not be taken up and pursued successfully in their initial stages by persons engaged in professional duties.

"If, however," he said, "the investigations at the universities are to be carried on by men who are subsequently to be leaders in their profession—and this is much to be desired—it is clear that there is the greatest need for such provision as will enable those who have completed their university course to stay on for one or two years engaged upon this work in the university laboratories before they become absorbed by their professional duties. If we are to maintain a high order of advanced work at the universities, and to supply the professions with men who have learnt to know the meaning and the method of such work while they are still able to learn, nothing can be more useful than scholarships and fellowships for advanced study and research which will enable students to remain for a post-graduate period. In the medical profession I am glad that opportunities are now being provided to an increasing extent; and foremost among these we have to acknowledge the great debt which the profession, and indeed the whole world, owes to Mr. Otto Beit for the noble benefaction which he instituted early in the present year in memory of his brother. I believe that that and similar schemes are destined to play a tremendous part in the intellectual advances and the professional development of our country; the universities in whose schools the Beit Fellows will carry on their researches will also receive a great impulse which will enable them to fulfil more adequately their duty to higher learning and investigation. I venture to hope that the London School of Tropical Medicine, a school whose energies are so largely devoted to special and advanced study, values its connexion with the University of London, and derives real and substantial benefit from an intimate association with the University."

Dr. Miers pointed out in conclusion that in the earlier days of scientific research the telescope and the microscope could be turned upon almost anything in the hope of discovering suggestive objects of inquiry where the trail could be followed into the unknown region, but under present conditions research is more concentrated upon a special line of investigation out of which arises the danger that those whose attention is too much fixed on one thing may fail to perceive others which are equally discernible and equally important. That those who expect too intently any phenomenon may actually see it or hear it though it be not there, he illustrated by the following story. "When the tropical annexe of the Crystal Palace was burnt down a large concourse of people witnessed the conflagration, attracted by the extraordinary spectacle of the streams of

molten glass. It was known that a number of animals, parrots, and monkeys were kept in that annexe and were burnt to death. One ape had escaped to the roof, where it clung for a long time, unable to escape, and was literally roasted to death before the eyes of the agonised spectators, who were not only witnesses of its contortions, but also heard the poor creature's screams. After the conflagration it was found that the object which had excited such interest and compassion was a piece of tarpaulin."

Dr. Miers then pointed out that the same defect belonged not only to the senses, but to the intelligence, as it frequently happened that an acute and eager mind became so obsessed by some idea, distorting the judgment, that the victim of it was led to explain everything in the light of the fixed idea, and to ignore other possibilities. "In fact," he said, "many of the mistakes of investigators are made in this way. Now, I do not venture to suggest that scientific men are often deceived by their senses to see and hear what does not really exist, or be blind and deaf to phenomena that play an important part in their experiments or observations, though I do think quite seriously that this may sometimes occur; but I wish to remind you of the danger that scientific training and experience may quite easily predispose both the senses and the mind to this weakness. So far from being a good training for mental receptivity and alertness of sense, so far from fitting the observer to notice and interpret every trivial detail that may have a significance, the training of scientific observation, both in the laboratory and in the field, unless wisely conducted and corrected, may easily unfit the student for this very purpose. In science, as elsewhere, familiarity may breed contempt for important details. He who is practised in a certain line of observation may, in proportion as his senses and his intelligence become more acute in the appreciation of the events or the objects for which he is watching with expectant attention, become less and less able to appreciate properly anything else. I speak from some experience, for I have noticed both in myself and many of my pupils this failing. A mineralogist like myself, although quick to notice in laboratory experiments on minerals and crystals the slightest indication of the result that he expects, so that he sees things that would not be visible to the untrained observer, and although quick in the field to notice the minutest specks of the mineral for which he is searching, specks which would not be discerned by the unpractised eye, may be in other respects a deplorably unobservant person and fail to see the most obvious things. How far may this be partly the result of cultivating observation of a special sort?"

From this Dr. Miers concluded that the faculty which is cultivated by much of our scientific training and work is not readiness and certainty of observation so much as specialised memory; taken as a whole, he did not think that scientific men are better general observers than other people; indeed, he was inclined to think that the senses of a boy might be better trained to detect minute and unexpected details by the practice of field sports than by the special practice of a laboratory. He concluded this suggestive address by pointing out the minuteness and special character of much of the work in tropical medicine, and by urging that those engaged upon it should exercise imagination in their studies and be ever on the alert to see new developments.

THE POST-GRADUATES' MEDICAL COLLEGE AND POLYCLINIC.

INTRODUCTORY ADDRESS ON THE "TEACHING OF INSANITY TO THE MEDICAL STUDENT AND PRACTITIONER IN RELATION TO THE PREVENTION OF MENTAL DISEASES," DELIVERED BY ROBERT JONES, M.D. LOND., SUPERINTENDENT TO THE CLAYBURY ASYLUM AND LECTURER ON MENTAL DISEASES AT ST. BARTHOLOMEW'S HOSPITAL.

Dr. JONES began by quoting a recently expressed view of the Lunacy Commissioners that the inexperience of medical men as to the requirements of the lunacy certificate is responsible for much danger to the community, as it leads to the presence in that community of uncontrolled and uncared-for mental defectives. With regard to the number of mental defectives among us he gave some very ominous statistics, pointing out that while there are 160,000 certified insane persons in Great Britain and Ireland there are probably nearly as many more showing some intellectual deficiency, while in the last 50 years the estimated population of England and Wales has increased by 83·7 per cent., but the number of persons certified as insane has increased by 255 per cent. Dr. Jones pointed out that many students still divided the diagnosis of mental diseases into raving or frenzied persons and drivelling idiots, but modern science enabled us to obtain much broader and better ideas of clinical types of insanity. Moreover, he said, it is now recognised that the study of psychology must be a necessary preliminary to the study of mental disease, but unfortunately it is a difficult and subtle subject which does not fascinate the average student, especially in England. "The study of psychology," he continued, "and especially of the period of childhood, is therefore superlatively necessary to discover changes in the personality, to interpret the meaning of undue shyness or seclusiveness, to mark changes in the normal instincts, the growth of anti-social tendencies, of abstraction, of fondness for the mythical and the weird, or of modifications in the faculty of attention, for all of these may eventually be revealed in some unexpected psychosis. We meet many examples of these in the cranks, singularities, eccentric and anomalous persons which constitute society; we know of agitators, dreamers, street orators, and so-called conscientious objectors. Some of these are only ill-balanced individuals, often intellectually bright, but with a lack of emotional stability, showing either exhilarated excitement or nervous despondency and apparently without sufficient cause. Others among them are moody and variable, with uncontrolled will power, unstable in purpose, easily persuaded and liable to undue suggestibility. To this class belong the 'ne'er-do-wells,' the moral delinquents, and many of the so-called 'unemployables.' No better description of these can be given than to term them constitutional neuropaths and psychopaths. They are asymmetrical persons with an excess or a diminution of some or all of the mental powers. They are known at petty sessions as habitual law-breakers, hooligans,' street-loafers of both sexes, inebriates, and recidivists; to the Poor-law authorities as pauper casuals or vagrants; and they constitute a large number of the asylum population. There is among them all a loss of moral control and proper mental balance, they are obsessed with a keen desire for immediate gratification at the expense of future benefit, and they are characterised by a complete lack of those altruistic virtues upon which depends the welfare of the State as well as of individuals and families. Last year there were over 200,000 cases of drunkenness dealt with in the various police courts, and there appears to be a steady rise in juvenile delinquency! The proportion of indictable offences was lower 15 years ago, and of non-indictable 50 years ago than to-day! The army of vagrants numbers from 70,000 to 80,000. There are always two millions of paupers in the United Kingdom, averaging 20 per 1000, and this not including lunatics in asylums (of which there are over 130,000 in England and Wales), casual paupers, and vagrants. The cost of this burden is a bar to national progress. The total cost of maintaining our insane population is over 3½ millions, and this not including the cost of the inspecting officials with their staff. The cost of paupers is over 17 millions a year. In 1856–57 the cost of pauperism in Poor-law institutions was £16 per head. In 1906–07 it had risen to £29 per head—an increase of 76 per cent. Excluding the cost of the paid justiciary, we pay a million a year for our inebriate reformatories, our local and convict prisons, truant and industrial schools. Add to this the annual cost of our criminal population, including the net cost of the police, which is over 5½ millions, and we have a total of 6½ millions, annually spent upon our law-breakers, many of whom, as stated, are mental defectives. Surely a case is made out for investigating psychologically and sociologically the causes of mental disorders which are correctly defined as the 'bankruptcy of reason,' being the most melancholy and grievous of human afflictions, and also a blot upon our civilisation."

Dr. Jones proceeded to consider the reasons for believing that physical betterment is also an intellectual gain, and deplored the occurrence amongst us of reckless and unsuitable marriages and the general blindness to the evil results of alcoholism and sexual laxity. But he admitted that one of the results of the progress of civilisation must be a multiplicity of mental defectives, inasmuch as when life increases

in complexity there will be an increased liability to breakdown on the part of nervous and mental machinery. The responsibility of the medical man was therefore a grave and growing one in relation to mental defect; "he must be able to understand men, matters, and things," and be ready to give opinions based upon an intimate acquaintance with biological laws and the principles of heredity. The study of sociology he considered to be as necessary to the study of mental diseases as that of physiology is to the pathologist. "One of the chief reasons," he said, "why the medical student and practitioner should be familiar with these ancillary studies is that mental defect is best and most successfully treated in its early stages, and its recognition in this stage becomes therefore of superlative importance. The earlier that cases of mental disorder come under treatment the higher is the percentage of recovery, and the chances of recovery diminish progressively and considerably as the time before commencing treatment increases in duration. The successful treatment of all nervous and mental disorders means attacking them in the incipient stages; the stages of insomnia, of distracted attention, of sleeplessness, of reverie, or of capricious appetite. Gross mental decadence is associated with great neuronal changes, and analogy supports the belief that functional disturbances are attended by slight neuronal changes. It is therefore within the limits of possibility that these may be initiated by mental causes, and as cells are composed of granules of chemical substances which are not themselves alive, but whose activity determines the direction and arrangement of life processes, so the medical man, by a timely suggestion or by duly considered advice, may cause a change to occur in the working units of the cortical cells, thus arresting disease and opening the storehouses of accumulated energy, diverting their forces along normal channels. ..... I have shown how important is the study of brain functions and how these concern the biologist, the chemist, the physiologist, and pathologist, and I have enumerated the sciences which assist in the elucidation of mental disorders. To enable the student to grasp this difficult study, it is generally agreed that the different forms of insanity should be described in a systematic course and each lecture alternated with clinical pictures, illustrative of the theoretical course. The student should be encouraged to come into actual contact with cases by filling up and signing certificates and making himself familiar with the different forms for receiving and detaining cases of insanity whilst under treatment; cases such as those which come up for re-certification, and recent admissions, and he should also be permitted to watch the treatment, medical and moral, of actual cases. The course should be interrupted by microscopic and gross pathological demonstrations of diseased findings of the brain and other organs, and these contrasted with the normal state."

Dr. Jones concluded a serious and practical address by outlining what is being done in the different divisions of the United Kingdom for the prevention and treatment of mental disease. In Scotland he said that psychiatry has been more widely recognised than in any other part of the three kingdoms; in Ireland the teaching was mainly clinical; while in England lectureships were attached to the various medical schools and attendance at these and in the asylums is compulsory. But he pointed out that there is no special recognition of mental disease as a subject worthy of a diploma by the examining bodies.

THE WEST LONDON POST-GRADUATE COLLEGE.

INTRODUCTORY ADDRESS ON "SPECIALISM IN MEDICINE," DELIVERED BY DONALD W. C. HOOD, M.D. CANTAB., F.R.C.P. LOND., CONSULTING PHYSICIAN TO THE WEST LONDON HOSPITAL.

Dr. HOOD, after expressing on behalf of everyone present their deep regret at the death of Mr. C. B. Keetley, proceeded to point out in incontrovertible terms the necessity which nowadays exists for post-graduate teaching, alluding at the same time to the fact that not only the taught but the teachers obtained the greatest possible benefit from such courses of demonstrations as were given in the wards of the West London Hospital.

"We often," he said, "have with us those who come from all quarters of the globe, and they bring information and experience of those various tropical diseases with which we physicians are but poorly acquainted. Personally I shall always owe a debt of gratitude to many who have been my companions in my visits to the hospital, and who have so often aided my investigations by bringing their special knowledge to our mutual benefit. Abroad in various climes the practitioner is in daily touch with affections of the blood, liver, or spleen but rarely met with here, and thus in many instances of abnormal symptoms or irregular course of disease we may, by a comparative study, obtain a better insight into the disease process, and possibly we may be able to bridge over the gap or supply that missing link which has been wanting, and which may enable us to make a correct diagnosis, otherwise impossible. The far-reaching effect of malaria conditions with its often perplexing sequelæ may be of daily occurrence in the life of many a graduate, and may permit his making a certain diagnosis which to those less experienced is but a guess."

At this point Dr. Hood quoted Huxley's apprehension lest science should be crushed by the weight of the gifts which she demanded from nature. There was a time, said Huxley, when men of science would aspire to the possession of an all-round acquaintance with natural history, but nowadays specialism is the leading characteristic of science and is becoming more and more embarrassing. What Huxley said 20 years ago of natural science as a whole Dr. Hood found to hold true now of medicine. "One of the most remarkable changes," he said, "which has taken place in medicine both with regard to its scientific and practical side has been the enormous increase in specialisation. It is worthy of a moment's thought and reflection as to whether this is all 'real gold,' and whether the extreme specialisation of matters connected with pure medicine, as it is called, is of benefit to the common weal. Extreme specialisation in medicine is a growth of about the last 25 years, and attention may be said to have been called to the fact at that time in an article by the late Morell Mackenzie which will be found in the *Fortnightly Review* for 1885. ..... There can be no doubt that some of our principal centres of medical education were slow in recognising the importance of providing their students with the means and opportunity for acquiring special information and dexterity in the use of special instruments for research and inquiry. It is only common sense that with the enormous increase in knowledge of both surgery and medicine the ordinary practitioner, whether he be surgeon, physician, or engaged in general medicine, cannot be armed at all points. Specialism properly regulated is a necessary corollary to increased, and rapidly increasing, knowledge of every branch of professional life. We all recognise the obvious truth, and our hospitals one and all maintain the principle in forming those special departments which add so vastly to their general utility, and which, as I have already remarked, you will do wisely in following the practice and technique. But there is a material difference in connexion with the special department of a hospital with its carefully-selected professors, and that of specialism as considered by a large proportion of the public. In hospital the special department is fed, maintained by skilled—if I may use the word—purveyors. There would be, I am afraid, a sad miscarriage of good if the selection of appropriate cases were left entirely in the hands of a hospital porter. Those of us who have had charge of wards appreciate to the full the advantages which result from our being able at any moment of day or night to call upon one of our colleagues who may have made special study of any case in which the complicated, unusual, anomalous symptoms are difficult of interpretation—cases in which some special symptom or congeries of symptoms lead us to wish for more detailed knowledge than we ourselves possess. The same holds good in our private work, and we are all grateful for those who frequently place at our disposal that special, peculiar knowledge which may enable us to substantiate our diagnosis, throw more light on the conflicting testimony of physical signs and symptoms, and so lead us to a more successful treatment of the sufferer we are called upon to advise. The seed of specialism is rich and good, and if only sown on appropriate soil must bear fruit a hundred-fold, and a bounteous harvest will follow in due course if only specialism be regulated by those who, by reason of their knowledge, are able to appreciate its advantages and limitations."

Dr. Hood proceeded to demonstrate that the abuses of specialism came from the misunderstanding of the public of

the limitations of medicine and their apparent desire to be treated by the charlatan rather than by the physician. He ridiculed in vigorous language certain popular crazes in therapeutics, and quoted the late Sir William Gull as one who never felt himself sufficiently well informed in general medical knowledge to become a specialist. The public, said Dr. Hood, took a very different view from Gull, considering that it is essential to their proper treatment that a limited and often prejudiced view should be taken of their symptoms, in proof of which he gave a typical sketch of the behaviour of a patient with Bright's disease who flies from neurologist to dermatologist, from dermatologist to ophthalmologist, and so on, frequently failing to consult the man who has made diseases of the kidneys his particular study. He closed his interesting address by saying: "Ill-regulated specialism, then, must always lead to the danger of routine treatment, and no better example could be cited than that of the treatment of disease of the heart. I know no organ which has been so unkindly dealt with. Whatever the character or form of disease, whether valve, muscle, fibrous tissue, as in pericardium, or nerve, or functional weakness, whether suffering from toxic conditions as seen with tobacco or influenza, whether showing signs of weakened, failing circulation as in angina, one and all they have been subjected to the same routine course. Why, I ask, do our heart cases do so well in hospital? Mainly from the fact that in treatment we use common-sense principles, looking upon rest in bed as being our sheet-anchor in a vast proportion of cases, and we do not send our patients to Nauheim. 'Has not rest been tried?' said one of our most distinguished physicians to a patient suffering from mitral disease, who had been subjected to every special form of treatment minus the one most essential and necessary. The more deeply we probe into the recesses of the human economy the wider our knowledge and scope of medicine, the more we shall be impressed by the fact that a healthy specialism can only be grafted on to some one or other form of the parent stock, that being clinical medicine. Specialism of a narrow order must invariably lead to faulty diagnosis and therefore faulty treatment. It does much to promote that evil we all so much deplore, the growth and vigour of all sorts and kinds of unqualified irregular practice. We may not at the moment have a Cagliostro in our midst, but there are hundreds who run that eclectic practitioner, that profound student of human credulity, very close."

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

PRESIDENTIAL ADDRESS ON "SPECIALISTS AND SPECIALISM," DELIVERED AT THE COMMENCEMENT OF THE SESSION BY PHINEAS S. ABRAHAM, M.D. DUB., F.R.C.S. IREL., DERMATOLOGIST TO THE WEST LONDON HOSPITAL, AND LECTURER ON DISEASES OF THE SKIN TO THE POST-GRADUATE COLLEGE.

[Dr. ABRAHAM, after expressing his high appreciation of the great honour which his election as President of the society had conferred upon him, said that not many years ago specialists and specialisms in the medical profession were not held in very high esteem in this country. Continuing, he said:—]

I think I am not far wrong in saying that until some 40 years ago most hospital surgeons considered themselves competent to perform any and every operation upon any and every organ of the body, and that every physician thought himself able to treat any and every possible disease. But science has advanced so rapidly in the last few decades that in these days he would indeed be a bold man who pretended to be an expert in every department of medicine and surgery, or tried to pose as a universal specialist. The growth of genuine specialism has been gradual, and it is still going on. Many a man who would deprecate being called a "specialist" is really one, or at any rate is being forced virtually to become one. In the course of his work his attention may be directed to some particular class of disease or operation. He learns all there is to be learnt about it, and perhaps adds something to the existing knowledge. He widens his experience with similar cases, and by degrees gets the reputation of being an authority on that particular subject. As is only natural, the general public will go to the man who has, or is supposed to have, the largest experience of the particular affection from which they suffer, and his brother practitioners also will seek his assistance and advice in cases upon which he has become an authority. Sooner or later he may find himself doing little or nothing outside of that special area, and he has indeed developed into a veritable "specialist," whether he likes to be called one or not. Most of the great specialists have thus been gradually evolved. Legitimate specialists, however, are not only made in that way; some go in for special work malice prepense—from natural inclination or from some other particular reason. But the wiser men of this class—in this country, at all events—do not "rush in" without a good general foundation or unless after long special study. In my opinion, the best equipped specialists in dermatology as well as in every other special department are those who have not only acquired a sound practical knowledge of general pathology and of the other subjects of the student's curriculum, but have also gained before attempting to specialise at least a few years' experience in the general practice of the profession. A man may afterwards work in the special department of his own or some other hospital, and I would advise him to attend the clinics of as many teachers of the branch he has chosen as he can, both in this country and abroad.

[Dr. Abraham then pointed out the harm that was done to "specialism" by the medical man, who with no particular special study and with no extensive experience of a subject suddenly decided to become a specialist. It was men of this class, he said, who were more prone to lend themselves to vulgar advertisement and to ignore the ethics of the profession in other directions. He continued:—]

It has been recently said that in the near future there will be nothing but specialists, hospital physicians and surgeons, and medical men in the Government services; in other words, that there will be no place for the general practitioner as we know him to-day. I believe that such a state of affairs is not likely to come to pass, for it would not only be detrimental to the profession in general but a serious loss to the public at large. The family doctor—the medical "guide, philosopher, and friend" of the household—will always be, I maintain, an important and, indeed, indispensable element in the medical world. With the more thorough education that is now at his disposal, and with his daily advancing knowledge, his patients will be less likely to leave him and independently seek the advice of the consultant and specialist, as some no doubt do at present. It is his function to advise in and treat all cases that he really understands and can adequately deal with; but I venture to think that in the long run he is well advised in obtaining assistance from experienced experts in cases which he is not sure of, or which are beyond his knowledge. It is true that many of the general public still imagine that if the "doctor" does not know everything in medicine and surgery, and honestly professes his ignorance, he cannot be a good doctor, or "clever," as they call it; but the laity are gradually becoming more enlightened in these matters, and are now more able to appreciate them in their true proportion than they could a few years ago. I know that some practitioners avoid consultations as far as they can, because after a consultation they occasionally lose their patient and see him no more; and it is possible that certain consultants and specialists have little hesitation in quietly appropriating such patients and regarding them as their own for the future. I am sure, however, that an honourable consultant or specialist does not knowingly act in that manner, and that if a patient who has been brought or sent to him by a brother practitioner comes again independently he informs the practitioner and tries to send the patient back. If this rule is occasionally broken by reputable men it can only be by inadvertence or forgetfulness. The friction which may thus sometimes occur between general practitioners and consultants would, I am sure, be lessened, or be, indeed, non-existent, if only we acted generously—in fact, as gentlemen—and remembered the old adage, "Live and let live."

In a recent correspondence which has appeared on this subject it has been suggested that no specialist or consultant should ever see a patient unless accompanied, or sent, by a general practitioner, and that no general practitioner should have anything to do with a specialist or consultant who sees patients independently. I am afraid that this idea must be regarded as a "counsel of perfection" and not practicable. We must not forget that there is still a certain amount of

freedom in this country and that the lay public also have their rights.

In conclusion Dr. Abraham said: "It must be admitted that at the present day advances in our knowledge of disease are more likely to be made—and are, indeed, being chiefly accomplished—by men who devote themselves to the study of particular subjects, than by those whose time and energies are fully employed in the routine of general practice. At the same time I am sure that every general practitioner must frequently in the course of his work meet with facts of interest or of novelty which ought to be recorded. I wish, indeed, that every member of our profession could always afford the time, and would more often take the trouble, to accurately report every circumstance that appears to him unusual in the course of the disease he is treating. Much valuable knowledge could probably be thus added to medical science, which is now 'bottled up,' so to speak, in the brain of the general practitioner.

One of the great objects of our late friend Mr. Keetley, and of those who were associated with him in the foundation of this society, was to afford the opportunity to the medical practitioners of the neighbourhood, and to the staff of the West London Hospital, to meet together, compare notes, learn from each other, and conjointly to advance medical and surgical knowledge. No one can say that the society has hitherto failed in this respect. May we continue to proceed on these lines, and I trust that this session which is now beginning will be not less fruitful than those which have gone before."

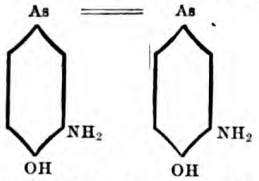
FURTHER EXPERIENCES WITH "606" (80 CASES).[1]

BY J. E. R. McDONAGH, F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS AT THE LONDON LOCK HOSPITALS.

BEFORE relating my further experiences with "606" a few words will not come amiss describing the *rationale* and the steps taken before a drug was discovered which, on the one hand, would kill the organisms in protozoal diseases, and, on the other, be non-toxic in that dose which would bring about their complete destruction—in other words, the action must be parasitotropic without being organotropic.

Experiments were first carried out with trypanosomes, and after several thousands of chemical substances had been tried with a view of discovering whether fixation of the organisms was possible, it was found that those having this power fell into three groups: (1) Arsenic and antimony; (2) azodyes—e.g., trypanrot, trypanblau, and trypanviolet; and (3) basic triphenylmethane dyes—e.g., parafuchsin, methyl-violet, and pyronin.

With pyronin, for instance, it was possible to produce a specific immunity in trypanosomes against the group to which it belonged, but not against a substance in groups 1 and 2. The chemotherapeutic action was studied by mixing trypanosomes with corresponding substances and observing microscopically their cessation of movements and swelling, and also *in vivo*, e.g., by gauging the curative action on infected animals. In this way a substance was found to have the power of killing spirilla of recurrent fever in as weak a dilution as 1 : 6,000,000; *in vivo* the effects were equally remarkable not only in combating the diseases due to spirilla, but also those caused by spirochætæ and trypanosomes, without being non-toxic in that dose which was able to bring about their complete destruction in 24 hours and after a single injection; this preparation was a dioxydiamido-arsenobenzol, or, as it is now popularly called, "606." The formula of "606" is represented graphically as follows:—



Atoxyl differs considerably from "606," since it is not potent except *in vivo*, as its action depends upon a reduction product, para-aminophenylarsenoxyd, and in the reduction the arsenic molecule becomes changed in such a way that all cannot be fixed, consequently people possessing a natural sensitiveness to arsenic might become poisoned by that portion which remained unfixed; and this is what actually happened. Further, several doses of atoxyl are required to one of "606." Before the drug was put upon the market Ehrlich drew attention to this possibility, and showed that it might be avoided by testing the patient's sensitiveness by means of either a Calmette or a von Pirquet's reaction with the drug before use; and those giving a positive reaction regarded as unsuitable for treatment.

Owing to the difficulty of using a solution of "606" for test purposes, I advocated arsacetin—a known toxic preparation. After testing several patients only two gave a positive reaction; both cases had been treated for some time with soamin, and not infrequently after an injection a red, painful induration formed at the site of injection, analogous to the intradermal reaction with tuberculin. Both patients received an injection of "606," and although ill for a few days responded remarkably, and as one had double optic neuritis which did not go on to atrophy, any test beforehand might be regarded as unnecessary.

Owing to the enterprise of other chemical manufacturers drugs similar to atoxyl were advertised as harmless and were used indiscriminately with sporadic disastrous results, for which Ehrlich was blamed. Therefore, it is scarcely to be wondered at that Ehrlich should take every precaution in limiting the use of this new preparation "606" to a few whom he could trust to test its efficiency and gauge its indications and contra-indications.

Both atoxyl and arsacetin have been largely employed in the treatment of psoriasis and lichen planus, and no harmful sequelæ have supervened—rather what one would expect, since the reduction does not seem to occur unless some protozoal disease is present to bring it about. "606" has also been tried in cases of psoriasis, lichen planus, and leukæmia without any great benefit arising therefrom.

Some of the preparations which fall into the three groups and which have a destructive action on the organisms *in vivo* do not destroy the same in a test-tube, but only inhibit their multiplication. For instance, Busk showed that paramecia could live for weeks in a solution of trypanrot, but were completely unable to propagate themselves.

Another action which some of the arsenical compounds possess is to kill some of the organisms, which results in the production of antibodies, which destroy the remainder.

The best results of cure obtained are, naturally, when the disease is at its height, when the body is saturated, so to speak, with the specific organisms, since the formation of antibodies may play even a greater part in causing their complete dissolution than the direct destruction of a few, and in these very potent preparations the smallest dose possible may suffice.

In the treatment of syphilis with "606" I have found that a much bigger dose is required to heal an early chancre than to cure completely a case of extensive gummatous ulceration, for instance, in a congenital syphilitic; therefore one is justified in assuming that the cure is largely due to the amount of antitoxin formed—a further proof of which the following is an excellent example.

If a mother after giving birth to a syphilitic infant be injected with "606," all the syphilitic manifestations in the infant disappear within a week after it is put to the mother's breast. The improvement is not due to the amount of arsenic the child receives, since none is found in the milk; it must, therefore, be due to the antitoxin produced in the mother by the death of her spirochætæ, and which is conveyed by means of the milk to the child. This fact is of considerable importance, since the risk of death in an infant injected with the smallest possible dose of "606" is enormous, owing to the amount of endotoxin formed. We do not yet know whether the cure obtained in a child in the way described is a permanent one, and Ehrlich's advice at present is to give the child an injection later, when it is in a healthier condition. Curiously enough, some of the dyes—methylene blue, for example—have a contrary action; they cause a tremendous increase of the parasites instead of destroying them, since their action is more organotropic than parasitotropic. Another factor not to be forgotten is, that after a single injection the protozoa may become immune to a further injection; that this is the rule with all the arsenical compounds is by no means the case, since patients who have had

[1] See THE LANCET, Sept. 3rd, 1910, p. 711.

a course of atoxyl or arsacetin respond equally well to an injection of "606."

In cases which have recurred owing to the initial dose of "606" being too small, it yet awaits to be seen whether a second injection will retain its equivalent action; protozoa do become immune to arsenic, so it is quite likely that even a larger second injection may fail to cure the disease. It is most important, then, to put the dosage on a sound basis, and experience has already shown that the doses first employed were too small. Two of my early cases recurred, and both received a second injection, which has fortunately been able to heal the local lesions; whether a cure has been produced it is yet impossible to say. The improvement following the second injection, although the dose was larger, was not nearly as quick as after the first, and I doubt whether it is going to be permanent; such being the case, it is foolish to give a third or more injections, one must then fall back on mercury. An adult should not receive less than 0·5 grm., 0·6, 0·7, and 0·8 grm. are quite safe; in fact, these are the doses which Professor Ehrlich has recently sent me.

The procedure of the modern chemotherapy, which has in innumerable animal experiments succeeded with one fell swoop in curing the severest of infections, is exactly analogous to that of surgery, which with one operation is capable of eradicating a disease; in both the instruments employed carry with them some slight degree of danger. As Ehrlich aptly says, surgery owns her success not to the principle of *primum ne noceas*, but to *primum ut profiteas*, and when from animal experiments we are sure that a true cure has been obtained, surely it is better to run the slightest risk than to deprive all of its benefit. One has only to see cases of malignant syphilis going rapidly downhill, uninfluenced by mercury and developing phthisis, improve in a fortnight beyond recognition, practically saved from death, to realise what this means. As the surgeon can discriminate between those suitable for a certain operation and those not, so will those with whom "606" has been entrusted be able to lay down definitely the indications and contra-indications for treatment.

Since my last communication I have tried injecting the drug in every possible form, and as regards the future course of the disease what form employed matters little provided the medium is an alkaline one. Since the pain in a nearly neutralised medium is so much less than in a strongly alkaline one, I always prefer to almost neutralise my solution, and as the bulk adds greatly to the pain, I am now able to produce an emulsion of not more than 6 cubic centimetres, and instead of injecting into the glutæi, I now inject under the trapezius on a line with the spine of the scapula, and midway between the scapula and the vertebral column, on the left side in right-handed individuals, and *vice versâ*. Injections into the glutæi necessitate the patient's lying in bed, and since the pain is often worse in this position than when standing up, patients begin to walk about the room on the second and third day, when all of a sudden they are seized with severe sciatica which may keep them bedridden for as long as three weeks, probably due to the gravitation of the injection mass downwards on to the sciatic nerve; and, further, early movements increase the local inflammatory reaction, so that a large swelling almost invariably forms, and it is not till this swelling has almost disappeared that the sciatica abates. Injecting into the shoulder one is below the brachial plexus, so there is no radiating pain down the arm and only a very occasional shooting pain down the back and up to the head. Not infrequently, immediately after an injection into the shoulder, especially in plethoric individuals, there is great difficulty in breathing owing to a spasm of the intercostal muscles on that side; this difficulty in breathing, which may be accompanied by coughing, does not usually last longer than a quarter of an hour, and in only one of my cases did the patient get a little blue; and as in this case the difficulty in breathing persisted for some time and pleurisy developed, I now always inject emphysematous patients in the glutæi.

The method I now employ of preparing the solution is first to rub the powder up in a mortar with 1 cubic centimetre of a saturated solution of sodium hydrate, adding to this 3 to 4 cubic centimetres of very hot water, then 3 drops of the standard alcoholic solution of phenolphthalein, and just enough glacial acetic acid till a fine yellow emulsion is formed, and finally a drop or two of the sodium hydrate solution until the emulsion is of a rose-pink colour on adding another drop of phenolphthalein. The emulsion is best prepared by the bedside.

Kromayer is now injecting the powder in liquid paraffin, and depends upon the alkalinity of the blood in producing a mono- or bi-sodium salt. Such a preparation is painless, but whether equally efficacious I cannot say.

Prophylaxis.—As a prophylactic the drug is powerless, since its constituents are not broken up unless acted upon by protozoa, but be syphilis diagnosed as early as it is possible to do, after a single injection of 0·5 to 0·6 gramme the spirochætæ can be made to disappear within 48 hours and no further manifestations of the disease appear.

Primary stage.—In no case which I have so far injected, where a chancre alone was present, have secondary symptoms developed, and those cases which gave a negative Wassermann's reaction before the injection remained negative with the exception of some which gave a positive afterwards, but all are negative at the time of writing.

CASE 1.—A Japanese, aged 26 years, came to the Lock Hospital with seven chancres on his penis and inguinal adenitis. The patient received an injection of 0·5 gramme into his shoulder and was sent home. When he came up a week later the chancres had completely healed, but the glands were larger. Eight days later still not a trace remained of the initial lesions, and the glands had returned to their normal size. In several cases I have noticed this enlargement of the glands after the injection, but the increase in size is not permanent.

The following is an interesting case complicated by sepsis, which abated after the injection.

CASE 2.—The patient, 35 years of age, developed a chancre in January, 1910. The sore became phagedænic and when the patient was admitted to hospital in July the penis had almost disappeared, the urethra opening under it as a separate structure; there were also two offensive ulcers above the pubis. Owing to the extreme septic condition an injection of "606" was given to see if it would have any influence in checking its further course. Seven days after the injection the condition ceased to spread, and 14 days later the ulcers had cicatrised and the stump of the penis had completely healed.

Owing to the great difficulty of admitting every patient I have treated many as out-patients, but this procedure does not commend itself, as they will not rest for a few days, with the result that a large lump forms at the seat of injection which gives rise to considerable pain and takes some weeks to disappear. A patient should keep as quiet as possible for at least four days.

Secondary stage.—It is the rule for all the symptoms to disappear after a single injection of from 0·5 to 0·6 gramme. Very rarely the rash is temporarily increased in severity analogous to the Jarisch-Herxheimer sign, which so frequently occurs when a patient is first put on a course of mercurial inunctions; the interpretation of such is that the dose given was too small and those cases reported did not receive more than 0·3 gramme.

CASE 3.—A man, aged 22 years, came for treatment with a urethral chancre, polyadenitis, and a diffuse macular papular rash. An injection of 0·5 gramme was given and within a week all signs of the disease had disappeared except for an increase in the enlargement of the inguinal glands, which have since gone back to their original size. Ten days after the injection Wassermann's reaction was positive; in fact, the serum had the power of fixing more complement than it did before the injection was given. On Sept. 29th Wassermann's reaction was just positive; the amount of complement fixed was less.

The most striking results so far obtained in the secondary period have been in cases of malignant syphilis of which the following is an excellent example.

CASE 4.—A man, aged 32 years, contracted syphilis in April, 1910, and as soon as the nature of the sore had been ascertained he was put under mercurial inunctions (ung. hydr. oleatis ℥i. nocte) and took hydr. c. cret. internally. A rash then appeared, but the patient did well under treatment for two months, when stomatitis, ulceration of the pharynx, and gummata of the skin and scalp developed, which tended to get worse the further mercury and iodides were pushed. The patient was so weak from dysphagia and anæmia, having lost 2 stones in two months, that he was admitted into the West London Hospital under the care of Dr. H. Pritchard,

to whom I am indebted for notes of the case, and received an injection of "606." Two days after the injection the throat was not so sore and on the third day there was no difficulty in swallowing, and the sores on the body showed marked signs of healing. Within a week the mouth and throat were normal, and within a fortnight every gumma had cicatrised, and the patient remarked that he had never felt better in his life.

Another case of malignant syphilis was essentially the same as the last except that there was an additional complication of pulmonary tuberculosis. After an injection the patient's cough subsided, there were no more night sweats, and although the physical signs were still present they did not appear to be so obvious.

Perhaps the most resistant syphilide to mercurial treatment is the small recurrent papular syphilide, or the lichen syphiliticus, of which the following case provides a good example.

CASE 5.—The patient, a woman, aged 38 years, was admitted, under the care of Dr. P. Abraham, to have an injection of "606," which she received (0·6 gramme) on Sept. 3rd, for a lichen syphiliticus on the face and other parts of the body, which had persisted for 15 months, and in spite of continuous treatment had never improved. On the third day the patient had delirium tremens; she had never had an attack before, but she was an alcoholic, and was under the influence of alcohol when admitted into the hospital. In a short time the patient recovered and the syphilitic lesions completely disappeared, leaving only slight pigmentation behind. Just as the patient was going to be discharged she developed erysipelas on the forehead from a case in the same ward; as a result of the rise of temperature her mental balance again became affected, but regained itself when the temperature fell. The patient has now quite recovered, is fully *compos mentis*, and it is scarcely to be believed that she had had a most stubborn syphilide on her face only a fortnight ago.

In no stage of syphilis is the action more apparent than in the tertiary, when the patients are usually very run down; a few hours after the injection the symptoms begin to subside, and within a week not only have the lesions healed or disappeared, but the patient's general condition is also markedly improved. Three cases I have had of women unable to work for two or more years who returned in three weeks, and, as one said, "feeling 10 years younger."

I have been struck by a group of symptoms which, for want of a better name, I will call vascular, and which a patient does not usually complain of, but the disappearance of which he calls one's first attention to after the injection. These subjective symptoms are præcordial pain and "heaviness," palpitations, irregularity of the heart beat—in short, a pseudo-angina; probably dependent upon an endarteritis of the small vessels. So constant are these symptoms that they should prove of great value in diagnosis.

CASE 6.—The patient was a housewife, aged 23 years. The date of infection was not quite clear, but there had been four pregnancies with evidences of syphilis. She came for treatment a year ago with a sore-throat and difficulty in speaking and swallowing solids. She was under the care of Dr. H. J. Davis, who very kindly asked me to give her an injection. The diagnosis of syphilis was unmistakeable, there was ulceration of the pharynx, the larynx, and the posterior nares; the uvula and part of the soft palate had gone. For one year the patient was treated with anti-syphilitic remedies without avail; her general condition became so bad, and the ulceration tended to advance, that she received as an out-patient 0·5 gramme in an emulsion of 6 cubic centimetres which I injected under the left trapezius. For three or four days the patient was extremely ill, had high fever, and sweated profusely. The further course will be best explained from a letter I received seven days later:—

> For 12 long months I could not eat anything solid, and even found it difficult to swallow liquids. But a few hours after your injection I found relief, much to my delight. Although it is only a week since you did it I feel a new woman and can eat almost anything.

The improvement in her general condition was really remarkable, her speech was no longer a whisper, and the ulceration had completely healed 11 days after the injection.

CASE 7.—The patient, aged 42 years, a housewife, was admitted with gummatous ulceration and elephantiasis of the left leg, the condition having been gradually getting worse since 1908. Syphilis was contracted in 1904. For this case I am indebted to Dr. H. G. Adamson. The affected leg was red and swollen from below the knee to the ankle-joint, there were several scars from old gummata and ten recent septic ulcers and a few abscesses filled with pus, which were just on the point of breaking down. The circumference in the thickest part was 12 inches. The ankle-joint was swollen and too painful to move, the patient could not bear pressure on the leg, and the pain was very acute when standing on it. The patient's general condition was not good, she was anæmic, felt ill, and had no appetite—in fact, looked as if she was under the influence of septic poisoning. On August 18th the patient received in the glutæi 0·4 gramme in an emulsion; the next night the temperature rose to 101·4° F., and the pulse-rate increased to 104; two days later both the temperature and pulse were normal. There was a slight trace of albumin after the injection. On the 21st the circumference of the leg had diminished by half an inch; the ulcers were quite clean and commencing to granulate, and the patient could move the ankle-joint. No albumin was present. On the 23rd the ulcers had healed. The leg measured 11 inches. The patient got up, and was able to put the foot to the ground without it causing any pain. On the 26th the leg measured 10¾ inches. The skin had regained its normal colour, there was no pain, the abscesses referred to above had aborted without discharging their pus, and the patient declared that she had never felt so well in her life.

Beyond the great improvement in the general condition the most important point in this case was the way in which the septic material, pus, &c., had disappeared without any supplementary treatment. On Sept. 15th Wassermann's reaction was negative.

The next case is one of extreme interest, as the patient was suffering from syphilitic meningitis and had double optic neuritis; the case was very kindly sent to me by Mr. A. W. Hare of Newquay, and for the notes of the condition before injection I am indebted to Dr. F. E. Batten who kindly saw the case with me.

CASE 8.—The patient, a man, aged 40 years, developed syphilis 11 years ago, but had no secondaries, and only took mercury internally for six months. In 1908 gummata developed in the skin and some of the cranial nerves became involved. Some improvement was obtained after several injections of soamin and potassium iodide internally. In January, 1910, the patient had diplopia, and was much troubled with headache and vomiting. In March he first noticed weakness of the right side of the face, and was treated with mercury and iodide, with only temporary improvement. When seen on Sept. 12th the condition was as follows: "There is an internal strabismus with diplopia due to paralysis of the right external rectus and weakness of the left external rectus. The movements of the eye dependent on the third nerve are good. The pupils react well and the vision is good. There is some swelling of both optic discs. There is paralysis of the right side of the face and both motor and sensory portions of the right fifth are involved. There is deafness on the right side, but the tuning-fork is audible when placed in contact with the mastoid. There is some unsteadiness in gait, but this would seem to be dependent on the diplopia. There is no rombergism and no weakness of the limbs. The knee-jerks are active and equal; the plantars could not be obtained, and the abdominal were difficult to obtain, but were equal. The articulation is somewhat nasal, but no weakness of the palate can be detected, although there is some difficulty in deglutition. The movements of the tongue are good. It seems probable that there is a circumscribed syphilitic meningitis at the base of the brain involving the right fifth, sixth, and seventh cranial nerves, and probably also the right eighth and ninth and the left sixth to a lesser degree. There is no evidence of any affection of the pyramidal tracts." The arsacetin reaction was positive and the patient stated that it was not uncommon to get a local red, painful hard swelling after a soamin injection. An injection of 0·5 gramme of "606" was given. The patient was very ill for a few days, but on the third day the temperature returned to normal and he declared that his hearing had improved. Within a week he could walk without a stick, all the affected nerves had regained some of their power, the improvement in the sixth and seventh being very striking. The injection was given on Sept. 12th and on the 28th I received the following letter from Mr. Hare:—

> Optic neuritis is still present, but the patient says his visual power has improved daily, especially during the last four or five days. The

third, fourth, fifth, sixth, and seventh nerves all show signs of improvement in function, but I cannot find any increase of hearing on the right side, though the patient says there is. Swallowing, respiration, and heart's action all improved. To-day the heart beat was perfectly regular at 78, whereas I have often found marked irregularity both as regards rate and strength. I am very glad you have so successfully carried out the treatment and I must congratulate you on its probable successful issue, as I think there could hardly be worse cases than this to test the treatment upon.

Another letter, dated Oct. 12th, states that the optic neuritis has almost gone, eyesight greatly improved, and that the patient can walk 100 yards without staggering. The hearing has also greatly improved.

I am glad that Mr. Hare drew attention to the improvement of the heart's action, since several patients have of their own accord drawn my attention to the disappearance of the præcordial pain or "heaviness" after the injection.

Besides the cases already mentioned, the improvement in chronic superficial glossitis has reached far beyond expectation.

CASE 9.—I injected a soldier whose tongue was twice the normal size, deeply fissured and ulcerated, his condition having gradually got worse during the last five years. As in most of these cases of chronic glossitis, mercury had little or no influence upon it. One week after the injection the tongue had nearly regained its normal size, there was no ulceration, and the fissures were not nearly so deep, and the patient says that he has had more ease than he has had for some years. The injection was given on a Saturday, the man was on parade on Sunday, and shooting the following day. Unfortunately most patients suffer considerably more inconvenience than this, although the injection be prepared in the same way. Pain must depend far more upon the idiosyncrasy of the patient than upon the injection itself.

CASE 10.—Another patient with chronic superficial glossitis and two swellings on the tongue, which might have been either gummata or malignant disease, was given an injection as he was most anxious not to lose the anterior two-thirds of his tongue. The lumps completely disappeared and he said that he felt very much better.

Another case under mercurial treatment for two years without benefit showed almost a normal tongue 14 days after the injection. Patches of leucoplakia had even disappeared.

The risk of optic atrophy from "606" need scarcely be seriously considered, since no case of amaurosis is on record, and I have injected one case of bilateral optic neuritis without atrophy ensuing, one case of unilateral optic neuritis caused by injections of soamin, two cases of syphilitic choroiditis, and two cases of syphilitic iritis, which healed after a single injection. Professor Ehrlich has had now over 12,000 cases, and not one has had any eye trouble.

In parasyphilitic affections "606" will not be often indicated, since both tabes and general paralysis of the insane are usually too far advanced before treatment is started. If a case is obtained early the result of treatment is really marvellous, as the following case will show.

CASE 11.—The patient, aged 36 years, developed syphilis ten years ago, for which he was treated with mercury internally for three years. Owing to impotence and loss of control over the bladder and rectum of four years' duration he consulted Mr. Arthur Shillitoe, who found that he had unequal pupils (the inequality being due to an old iritis of the right eye) which did not react to light and there were no knee-jerks. As he gave a positive Wassermann's reaction Mr. Shillitoe very kindly asked me to give him an injection of "606." Within a week after the injection the control over the rectum had been regained, and the trouble of not being able to start the act of micturition had disappeared. The knee-jerks were slight, the pupils reacted sluggishly to light, and the very slight ataxia which was present before had now disappeared. Seen again on Oct. 12th, my notes state that vision in the left eye is greatly improved and that glasses can be dispensed with. Erections returned; can do exercises and walk without getting tired. No indigestion and præcordial pain. Knee-jerks returned, and pupils react to light. Wassermann negative.

Three cases of tabes with marked ataxia did not improve under the injection, but foreign reports state that lightning pains disappear under the influence of "606" In one of the cases where there was a perforating ulcer an injection had the power of producing granulations, but owing to the joint being exposed complete cicatrisation was impossible.

It is more than probable that a very early case of general paralysis of the insane might be cured, but once degeneration becomes marked no further improvement can be expected. In two cases in which I used the injections no benefit was received.

Two cases of hemiplegia giving a positive Wassermann's reaction, and probably due to syphilitic thrombosis, did not improve after an injection.

The following rather unusual case is of some interest.

CASE 12.—A patient developed syphilis some years ago and had the usual symptoms, for which he was treated thoroughly. The symptoms never entirely went away, and a rash would appear periodically and there would also be attacks of malaise and great enlargement of the glands in the neck (size of hen's egg). Potassium iodide in large doses caused temporary improvement. I gave an injection of "606," and a fortnight later received the following letter from the patient, who had suffered very considerable pain:—

> I can hardly express my delight in being able to inform you that I am beginning to feel my old self again. Every day I can note an improvement in the feeling of well-being. The rash has gone and the glands are going; those at the angle of the jaw are still a little enlarged but seem to be getting smaller each day; those in the neck are reduced to the size of small peas and shot, and there is now no pain or tenderness in them. The awful depression and shooting pains are relieved, and once more I am beginning to feel there is some pleasure in being alive.

One of the greatest uses to which "606" will undoubtedly be put will be in the treatment of syphilitic women and congenital syphilis. Since women may be syphilitic without having, or having had, any symptoms of the disease, every woman who gives birth to syphilitic children should be herself regarded as syphilitic, the proof being a positive Wassermann's reaction which is obtained in these cases, and an injection of "606" has enabled such women to give birth to normal children. If a child is born with obvious signs of syphilis it is dangerous to inject the infant owing to the amount of endotoxin formed which a weak and marasmic child cannot overcome. Fortunately, there is a better way of treating congenital syphilis, as the following case, reported by Taege, shows.

CASE 13.—A girl, aged 19 years, with condylomata from which spirochætæ were obtained and who gave a positive Wassermann's reaction, bore on July 4th a marasmic child which weighed 4½ pounds. On the 13th pemphigus bullæ on the soles of the feet and paronychia of the fingers developed. On the following day the mother was injected with 0·3 gramme of "606." On the third day the lesions showed marked improvement and no spirochætæ were to be found in the condylomata. The child was suckled straight away by the mother, in consequence of which on the second day the symptoms increased in severity, to suddenly disappear with such extreme rapidity that on the fifth day the greyish colour had been replaced by the normal rose tint of the skin, the paronychia had vanished, the bullæ had become almost imperceptible, the child cried instead of whimpering, and took the breast eagerly. On the 29th the child weighed 8 pounds and showed no symptoms. The cure of the child is due to the antitoxin elaborated by the death of the mother's spirochætæ and conveyed to the child through her milk, no arsenic being found in the milk.

After every injection there is a leucocytosis which may sometimes be as high as 30,000; the increase is chiefly in the neutrophile leucocytes, and occasionally there is an eosinophilia. The usual count is about 17,000. The excretion of the arsenic takes roughly about a fortnight or three weeks after an intramuscular injection and the corresponding number of days after an intravenous, and since by the latter procedure the spirochætæ may not be completely destroyed in the time for safety many who use this route give a subsequent intra-muscular injection.

Albuminuria is an uncommon sequence of an injection. Constipation not infrequently appears, so on the second or third day it is advisable to order a laxative.

A rise of temperature after an injection is by no means an invariable rule and is not entirely influenced by the severity of the disease, although generally the severer the symptoms the greater is the rise of temperature. After an injection of "606" the tendency is for the Wassermann's reaction to become negative, the most usual time being between the third and fourth weeks. Some cases which had a chancre only and gave a negative Wassermann before injection gave a positive the week following, which again became negative, to remain so So far as we can yet say, in congenital syphilis the reaction remains positive. Regarding how not

infrequently syphilis is complicated by other diseases and associated with other infections, I have endeavoured to select such cases in order to study the influence "606" has upon them. Where syphilis is complicated with tubercle, which in the malignant form it almost invariably is, the injection exerts a beneficial influence upon the tubercular lesions. Secondary infection with streptococci and staphylococci is often cured along with the syphilitic processes it complicates; for instance, phagedæna of the penis and pubis was checked with a single injection. Coccal infection in a case of gummatous ulceration of the leg with elephantiasis was overcome by "606." On the other hand, an injection of "606" does not render a patient immune to either a streptococcic or a staphylococcic infection, since one of my cases developed erysipelas a fortnight after the injection, and two or three have since been troubled with furunculosis in a mild degree. Many of the patients were suffering concurrently from gonorrhœa, but on this disease "606" exerted no influence either for better or worse.

When dealing with the action of a new drug which cannot be regarded as entirely harmless it is just as important to record one's failures as successes. In a case of leprosy not the slightest good result was produced by an injection of 0·5 gramme. One man's death was hastened by the injection, a case of supposed cerebro-spinal syphilis, which turned out post mortem to be a case of disseminated sarcoma. The patient was in an extremely bad condition, could hardly move, and had anæsthesia up as far as the neck. Death ensued on the second day. Both the blood and the cerebro-spinal fluid gave a negative Wassermann's reaction; unfortunately, the test was not carried out until after the injection had been given.

The last-mentioned case is most instructive, as a similar one will befall many when the drug is put upon the market. So let me advise the precautionary step of testing the patient by means of the Wassermann's reaction before the injection is given, as unless this is done several non-syphilitics will be treated with "606." It is absolutely useless in a case of syphilis to rely upon history, since a man will often say "Yes" when the question of his having had the bad disorder is put to him, when probably it was only a soft sore or gonorrhœa from which he was suffering.

Patients who have had one or two attacks of hemiplegia, advanced cases of tabes, and general paralysis of the insane should certainly never be treated. Cardiac disease, marked arterio-sclerosis, and Bright's disease are contra-indications. In one case—that of an alcoholic—delirium tremens commenced on the third day after the injection, and the patient's mental condition was not normal until a week later. To what extent the delirium tremens was dependent upon the injection or to the stopping of the alcohol it is impossible to say. We know that it is not an uncommon sequence after any surgical interference.

An emphysematous plethoric man, aged 50 years, developed pleurisy on the side of the injection on the second day. In two cases only did a rash develop after the injection, curiously enough limited to the limb where the injection was made; in both cases the rash was a typical erythema iris, which only lasted for a few days. A condition simulating angioneurotic œdema appeared in a congenital syphilitic who had general paralysis of the insane, but it lasted only for about 24 hours. The cases which did not respond are mentioned above.

So far two cases have recurred; both had extensive ulceration of the nose besides gummata elsewhere; both were injected on August 3rd with 0·4 gramme and on Sept. 10th both patients noticed a redness of one side of the nose, which in a few days became ulcerated. They both on Sept. 24th received a second injection of 0·5 gramme. It is probable that in both these cases the initial dose was too small. It will probably take years before we shall be able to regulate the dose on a sound basis. Should that be the case and even recurrences occur, the patient's general health is so much benefited by the initial dose that they would be in a better condition to be treated with mercury if necessary.

Fortunately, not a single case has developed secondary symptoms in which the chancre was the only one when the injection was made, and animal experiments also go to prove that a single injection is capable of producing an absolute cure, since Neisser was able to re-inoculate apes a second time with syphilis. A second attack in man is regarded by many as impossible, probably due to the inefficiency of mercury in producing a cure; therefore we shall no doubt see several such cases which have previously been treated with "606."

Much has yet to be learned before the final word on this wonderful remedy is given; one can say that the dangers have been extremely exaggerated, since only 12 deaths have occurred in 12,000 cases, and in many of these the injection was given as a last resource. This being the case, and there not having occurred an instance of visual disturbance, the drug will not, in my opinion, fail to achieve the object which its talented discoverer Geheimrat Professor Ehrlich had hoped for it.

Harley-street, W.

A CASE OF BENIGN CYST OF THE HUMERUS.

BY HUGH LETT, M.B. VICT., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE LONDON HOSPITAL.

(*With a Pathological Report by* HUBERT M. TURNBULL, M.A., M.D. Oxon., *Director of the Pathological Institute, London Hospital.*)

THE patient, a boy, aged 13 years, was brought to the London Hospital on August 14th, 1909. He said that he had been knocked down and had fallen on to the right shoulder. When he got up the arm was painful and he could not move it. On examination the upper third of the shaft of the right humerus was much enlarged. It was firm, and the whole thickness of the shaft appeared to be uniformly involved, the swelling gradually shelving into the normal bone below. No eggshell crackling could be detected. The humerus was fractured about 2 inches below the upper epiphysis through the lower part of the enlargement. A skiagram (Fig. 1) showed expansion and rarefaction of the upper 3 inches of the diaphysis, limited above by the epiphyseal line and below by a well-marked concave margin of slightly sclerosed bone. The bony wall was well defined, but extremely thin, and at the lower end there was a transverse fracture with slight lateral displacement. The upper half of the swelling was crossed by a few trabeculæ, but otherwise the whole area was much less opaque than normal bone, though the opacity varied slightly in different parts of the swelling.

The previous history of the case was of great interest in that the boy had been in hospital two years before with the bone in a very similar condition of expansion and rarefaction, and with a fracture at the level of the surgical neck. Six days previously a man had pushed him on the shoulder; this was followed by pain which was exaggerated on attempting to move the arm. A diagnosis of sarcoma with spontaneous fracture was made, and amputation was advised. This, however, was refused, so the boy was discharged with a poroplastic shoulder-cap and the arm in a sling. Up to the day of the injury he had had no pain and had not noticed any swelling of the arm. The fracture united, and to quote his own words: "The arm got quite well and there was nothing the matter with it," until the accident on August 11th, 1909. Otherwise his previous history was uneventful, except for tuberculous disease of the right hip in 1899, with subsequent abscess formation and sinuses. Ultimately the hip-joint was excised. As far as the mother knew he had never had rickets, and he showed no signs of it now. There were two other children, aged 13 and 8 years respectively, who are both healthy. The mother was unaware of any tumour formation in members of her or her husband's family.

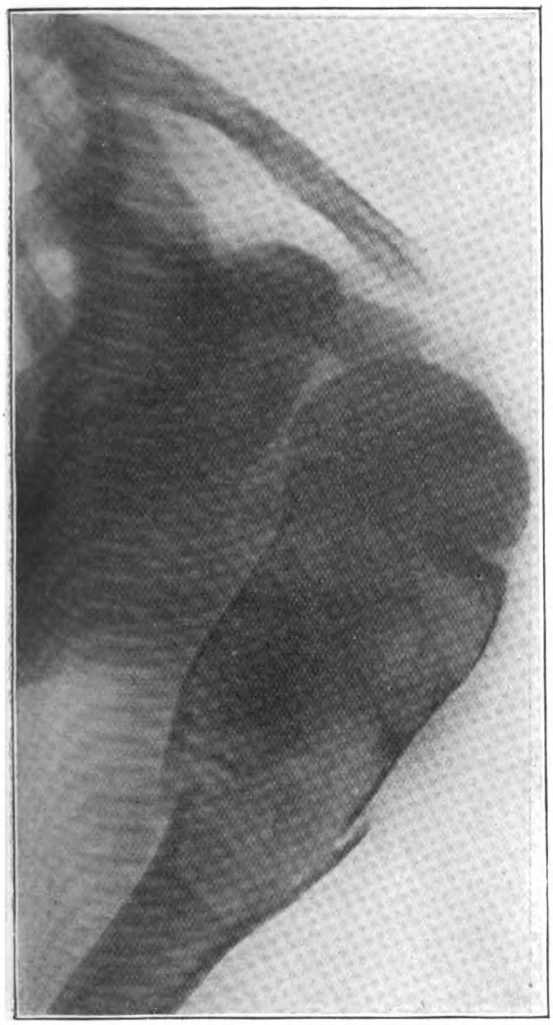
Operation was performed on August 20th, 1909. An incision four inches long was made on the antero-external aspect of the arm. The periosteum was exposed and appeared to be normal; it was then reflected from the expanded bone, but while this was being done the raspatory broke through the thin shell and a yellowish mucoid fluid escaped which was stained with blood. As rapidly as possible the whole of the affected part of the shaft was stripped of its periosteum and excised, leaving the epiphysis above and healthy bone below. The diaphysial side of the epiphysial line was gently scraped and the humerus was reconstituted. This part of the operation consisted in replacing the bone which had been removed by an ebony rod, such as is used for securing the intestine

outside the abdomen in the operation of colotomy. A distinctive feature was that the rod tapered to a point at one end, while the other was blunt, so that it resembled a sharpened pencil. The point was inserted into the epiphysis and the blunt end into the medullary cavity of the bone below. In this way the epiphysis was firmly joined to the shaft by a rigid rod. The periosteum was then sutured round the rod and the wound was closed. Healing took place by first intention and subsequent progress was uneventful. A poroplastic splint was moulded to fit the shoulder and extended down the forearm as far as the wrist, the elbow being flexed to a right angle. The splint was secured by straps passing round to the opposite side of the chest. Two months after the operation the splint was removed and the patient was given regular massage. At the present time the movements of the right upper extremity are perfect, and the muscles are rapidly increasing in size. The new bone is firm, straight, and regular, but slightly thicker than the left humerus; it is, however, three-quarters of an inch shorter. The skiagrams Nos. 2, 3, and 4, taken by Mr. Wilson and Dr. Gilbert Scott one week and two and six months respectively after operation, show the gradual deposit of new bone and some absorption of the ebony rod.

The clinical diagnosis of a benign bone cyst presents considerable difficulties, but a thoughtful consideration of the history and physical signs and, above all, a careful interpretation of a good skiagram will ensure a correct diagnosis in the majority of cases. There is often little or no pain, and it is not until a fracture takes place that attention is drawn to the bone. In the present case the boy had no pain before the first fracture, and when the bone had united he had no further trouble until the second fracture occurred. On the other hand, there may be a good deal of pain, as in a case recorded by Jones and Morgan. The cyst was situated in the proximal phalanx of the index finger, which had been swollen for some years. At an early period pain was absent, but it developed later, radiating at times to the shoulder, and finally becoming so severe that the patient was hardly able to carry on her business as a dressmaker. In other cases pain is only noticed a few weeks before the patient comes under observation, although the cyst may be of considerable size. With the pain there is usually a certain amount of disability.

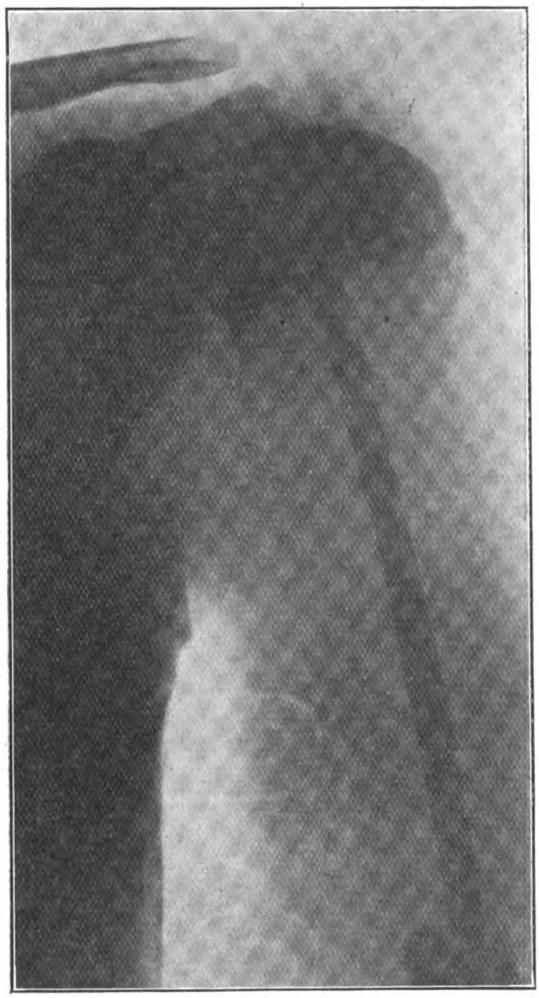
As a general rule these cysts give rise to little pain or inconvenience until they have attained a considerable size, and swelling of the bone is often the only symptom noticed by the patient. But even this may not attract attention until pain, disability, or fracture leads the patient to seek advice, although sometimes, especially in adults, the enlargement of the bone has been noticed for many years, possibly

Fig. 1.



Showing the cyst with fracture. Note the even expansion of the bone, and cupping of the shaft at the lower border of the cyst.

Fig. 2.



One week after operation, the rod *in situ*.

since childhood. As might be anticipated, when cysts occur in such superficial bones as the tibia and phalanges, the enlargement is recognised much sooner than in the case of more deeply seated bones.

The relation of these cysts to injury is an interesting one, and it has often been discussed. Sometimes the history is so definite and the injury so severe that much support is given to the theory that at any rate some of these cysts are traumatic in origin. Beck[1] describes two cases. The first was that of a boy, aged 10 years, who had fallen 11 months previously into an excavation in the street; the fall was followed by intense pain, and a fracture was suspected; the boy was in bed for two days. Four weeks later he fell again, and was in bed for four weeks. A swelling of the size of a filbert was then detected near the spine of the tibia. Six months later he had another fall, and was in bed for six weeks; after that he limped, and the swelling became still larger. A typical cyst was found extending to the epiphysial line; the walls were lined with a smooth membrane, and the cavity was traversed by a few osseous remnants and contained blood-stained serum.

The second case was that of a girl, aged 13 years, who had slipped downstairs eight months previously. The left ankle became swollen and painful, and she was not able to stand again. A cyst was found in the lower third of the tibia; the walls were lined by a layer of greyish-white substance which consisted of cartilaginous tissue, with round cells, and myxomatous and degenerated tissue. The cavity contained black viscid serum.

P. Glimm[2] mentions the case of a boy, aged 12 years, with a cyst in the upper end of the femur, who dated the onset of pain from a fall. Tietze[3] alludes to a girl with cysts in the right femur and tibia, who had had pain in the right thigh ever since a fall on ice 13 years previously. Similar cases have been described by Bloodgood,[4] Buchanan,[5] and others.

The following case described by Glimm[6] is attributed by him directly to the injury, and probably correctly so. A man, aged 25 years, had a severe blow on the anterior border of the tibia six months previously; he was in bed for three weeks with swelling and ecchymosis. The X rays and subsequently operation revealed a cyst of the size of a large plum in the thickened cortex; it had no connexion with the medullary cavity and was filled with blood. Glimm considered the case one of aseptic osteo-periostitis. This cyst

FIG. 3.

Two months after operation. The rod can still be seen indistinctly.

FIG. 4.

Six months after operation, showing the formation of new bone.

differed from the majority of bone cysts in being situated in the cortex instead of in the medulla, and instead of the bone being thinned and expanded it was actually thickened.

Müller [7] found that in 40 cases of bone cysts no less than 27—i.e., 67·5 per cent.—occurred in patients under 20 years of age, and 50 per cent.—that is, 20 out of the total 40—in patients between 10 and 20 years. Of the rest, 6 occurred in patients between 20 and 30 years. He also found that the majority of cysts are met with in the big long bones, the femur, tibia, and humerus being responsible for 38—that is, 76 per cent. of 50 cysts occurring in 43 patients. Cysts were most frequently found in the femur, 38 per cent. occurring in this bone, 22 per cent. in the tibia, and 16 per cent. in the humerus. The cysts may be multiple, several bones being affected in the same patient.

As the cyst develops the cortex is expanded and progressively absorbed until there is only a very thin shell of bone under the periosteum. A fracture then results from a very slight injury, or even from muscular action, though it may take place before this extreme stage is reached from a degree of violence which would not cause a fracture in a normal bone. In a number of cases the patient first came under medical observation on account of the fracture, the presence of the cyst having given rise to no symptoms previously, or at any rate to symptoms which were so slight that they were neglected by the patient. Such cases have been recorded by Glimm, Bloodgood, and others. The case which I have recorded is of interest in that fracture occurred on two separate occasions, at an interval of two years. Another point worthy of notice is that the first fracture united firmly, and the arm gave no further trouble till the second fracture took place.

Diagnosis.—Although in a certain number of cases the nature of the bony swelling is suggested by the history and physical signs, in the vast majority a definite diagnosis cannot be made until skiagrams have been taken and carefully examined. In the absence of an X-ray examination the diagnosis will lie between a benign cyst, myeloid or central sarcoma, certain inflammatory conditions, such as abscess, osteitis albuminosa, and so on.

Corson [8] reports a case of a cyst in a girl, aged 21 years, who had had an attack of typhoid fever at the age of 15 years. At 17 years of age she began to have pain in the right arm, and in her eighteenth year, while she was being helped from a train, the right humerus was fractured at the junction of the middle and lower thirds, where she had previously had most pain. The bone united, but the pain persisted. When the bone was finally explored the periosteum was found to be thickened and very adherent, the bone was very thin, and there was a cavity measuring 8 by 3 centimetres, containing clear brownish fluid. No bacteriological examination was made, but the thickening of the periosteum and its adhesion to the bone suggest that the condition was primarily an inflammatory one, possibly a typhoid osteomyelitis.

Eggshell crackling, if it can be obtained, will suggest a myeloid sarcoma or benign cyst, though very occasionally it is met with in other central tumours of bone.

The diagnosis will finally be made on the result of the X ray examination, though Jones and Morgan [9] say that a benign bone cyst cannot be differentiated with certainty from a slow-growing medullary sarcoma from X ray examination alone.

In a skiagram the cyst appears as a clear area in the expanded bone, reaching in a cyst of large size almost to the circumference, so that the actual bony cortex is reduced to a mere shell. A most important feature is the regularity of its outline. The bone has apparently been evenly expanded, so that what is left of the cortex is of a corresponding thickness on opposite sides of the cyst, and, further, the shell of bone presents a somewhat uniform density to the X rays. These cysts, when occurring in patients under 20, are generally found in the neighbourhood of the epiphysis, and it is important to note that they do not penetrate the epiphyseal line and invade the epiphysis.

Trabeculæ are often seen crossing the clear area, but Lexer is inaccurate in giving this as a point of differentiation from myeloid sarcoma, for bony trabeculæ are seen in these tumours.

There is yet one other point of interest, which is well shown in the first four figures in Jones and Morgan's article, and to a certain extent in our own case—namely, increased density of the bone immediately surrounding the cyst. In our case this is only seen where the bone limits the cyst below, but there is here a distinct appearance of sclerosis. The thickening of the bone seen in the case of an abscess enables us to exclude that at once, but a myeloid sarcoma presents greater difficulties. The typical features of a myeloid sarcoma are the irregularity of its outline, the varying thickness of the bony cortex, and the spreading of the growth more rapidly to one side or the other, so that it is asymmetrical, and does not present the uniform expansion of a benign cyst.

It often happens that the diagnosis is uncertain until the bone is actually opened at the time of operation. But then the escape of the serous or mucoid contents, which are sometimes blood-stained, the absence of growth or at the most the presence of cartilaginous masses in the walls of the cyst, and in many cases the presence of a lining membrane, leave no room for doubt.

Sometimes a bone cyst represents a myeloid sarcoma which has undergone extensive degeneration (Tietze [10]) but in this case, if other means of diagnosis fail, microscopical examination of the wall of the cyst will solve the difficulty.

Mr. F. S. Eve [11] has recorded an interesting case of a central sarcoma of the tibia involving the whole length of the bone. In the upper half the growth had undergone complete cystic degeneration.

Cysts may form as the result of osteitis albuminosa without any necrosis (Riedel [12] (Jena) and others), but in these cases one would expect distinct thickening of the bone and possibly of the periosteum. A bacteriological examination of the fluid might be positive.

Treatment.—In considering the treatment of this condition, we must not only cure the patient, but at the same time we should ensure a useful limb; this is especially important if a great part of the shaft of the bone is involved and the bony tissue replaced by the cyst.

Bloodgood, Sonnenburg,[13] and others were content with incising the bone, scraping the cyst wall, and packing the cavity with gauze. This gives a satisfactory result in the end, but it entails a tedious convalescence, and is not applicable in the case of a large cyst, especially if associated with a fracture. If the cyst is a small one, it is far better to scrape the walls thoroughly, sew the periosteum together, and close the wound, allowing the cavity to fill with blood clot. This will in time be absorbed and replaced by bone. Beck has slightly modified this by curetting the cavity and then pressing the osseous walls together.

Alternative methods are filling the cavity with decalcified bone, Mosetig-Moorhof's iodoform wax, or injecting paraffin, as suggested by Mr. A. J. Walton [14] in the treatment of chronic abscesses of bone. In the case of small bones resection is a suitable form of treatment, and was carried out by Müller on a patient who had a cyst of the fourth metatarsal. If, however, the cyst is so large that it occupies a considerable part of the shaft and little more than a shell of bone is left, and the bone is an important and independent one, it is advisable to provide an internal splint which will act as a scaffold and be a rigid support for the periosteum and other soft structures until the new bone is formed.

Mr. Harold Stiles by subperiosteal resection of the affected part of the diaphysis and subsequent suture of the periosteum has obtained some admirable results in the treatment of tubercle of the diaphysis of the bones of the leg and forearm. If, however, the femur or humerus is involved extension for some weeks is necessary to prevent shortening and angular deformity.

Lexer [15] in 1906 recorded a very successful case. The patient, a boy aged 14 years, had a cyst in the upper third of the humerus. The affected part of the bone was resected subperiosteally, and the deficiency made good by inserting a piece of a fibula which was removed with its periosteum from a recently amputated limb. The periosteum was sewn up,

the wound healed well, and the ultimate result was most satisfactory.

Alexis Thomson [16] recently showed a boy, aged 11 years, before the Edinburgh Medico-Chirurgical Society in whom the middle third of the humerus had been resected for sarcoma, a portion of the fibula being inserted in its place.

In our case the special points for consideration were the extremely thin, bony shell in the upper third of the bone, the fracture through this thin bone, and, lastly, the fact that the cyst extended up to the epiphysis. It was obvious that a thorough curetting would lead to further fracture of the bone, and that unless the proper distance between the epiphysis and shaft were maintained the ultimate result would be very bad; there was also the difficulty that the small epiphysis could not be controlled by any ordinary external splint. It occurred to me that an ordinary colotomy spigot would fulfil the necessary conditions. The periosteum was, therefore, stripped off the bone and the diseased part resected. Healthy bone was sawn through below and the upper end was twisted away from the epiphysis. The point of the rod was inserted into the soft epiphysis and the blunt end into the healthy medullary canal of the shaft below; in this way the epiphysis was fixed and maintained at its proper distance from the remaining shaft, and it was hoped that by sewing the periosteum round the rod the shape of the bone would be preserved. The subsequent history of the case is uneventful. New bone was gradually formed from the periosteum, and at the present time, fourteen months after the operation, the affected arm is as strong and as useful as the other.

The special points of interest in this case are the typical history, the two fractures from slight injury occurring at an interval of two years, the simple method of fixing the epiphysis to the remnant of the shaft, and the satisfactory shape and quality of the new bone.

Pathological Report by Dr. TURNBULL.

Macroscopic.—The specimen consists of a portion of bone about one and a half inches long. The bone is devoid of periosteum. The cortex is dilated in the upper part to form a thin, brittle shell which bounds a cup-shaped cavity in the upper part of the medulla. From the floor of this cavity a vertical septum projects for a short distance. The inner surface of the cavity is not quite smooth. A little blood clot and some tough, yellow, opaque tissue are adherent to it. The septum is of a rusty brown colour, and is tough and pliable. On vertical section through the centre of the bone the medulla for three-quarters of an inch below the floor of the cavity is found to be occupied by an abnormal tissue which also forms the septum. This tissue is red and gelatinous, with some minute, grey, refractile areas which suggest cartilage. Gritty particles can be felt with the point of the knife. This tissue is sharply limited from red marrow which lies beneath it. The corticalis in this lower part is of normal appearance. It is hard and of compact structure. It gradually thins to form the wall of the cup-shaped cavity.

Microscopic.—Small portions of the tough tissue adherent to the inner surface of the cystic cavity were removed, cut upon the freezing microtome, and stained in methylene blue and in hæmatoxylin during the progress of the operation. Larger portions of the same tissue were embedded in paraffin without decalcification. Finally, a portion of the bone, including the floor of the cavity above and the normal medulla below, was rapidly decalcified in nitric acid. Unfortunately, in order to prepare the report quickly, paraffin embedding was employed and this necessitated the removal of the greater part of the cortex.

Vertical sections of the bone show five zones of different appearance which merge with one another.

1. The surface towards the cavity is bounded in most of its extent by a zone of tissue which resembles in structure the portions of tissue removed from the lining of the cavity for the preliminary examinations.

The tissue consists of a net of broad moniliform hyaline bands separated by narrow clefts. In places the clefts widen out into larger areas of cellular tissue of the same structure as the stroma of the next zone. The hyaline bands contain no nuclei. Stained by van Gieson's method they are red and show whorls of ill-defined, very fine, more deeply stained fibrils. In some sections a few of the bands are impregnated by calcium. They do not give the staining reactions of cartilage, but appear to consist of an osteoid tissue in which there are no bone cells.

The cellular tissue in the clefts has a very pale matrix, which is stained a faint yellow in van Gieson. In this are relatively few spindle and stellate cells, which anastomose by long delicate processes. The nucleus is elongated oval. The cells are very uniform in size, shape, and staining reaction. The outermost cells lie flat upon the hyaline bands. In the centre of the cleft there is usually a capillary which is lined by a single row of spindle cells. There are many extravasated red corpuscles in this cellular tissue and much intra- and extra-cellular pigment. This pigment gives an iron reaction when treated by Turnbull's blue method. There are also considerable numbers of lymphocytes and an occasional plasma cell or eosinophil leucocyte.

The surface exposed to the cyst cavity is covered by red blood corpuscles with some fine fibrin filaments (Wiegert-Gram stain). Immediately beneath this the tissue appears to be degenerate. The hyaline bands stain feebly and the spindle cells in the clefts between them are not visible. Numerous red corpuscles are present here in the clefts.

2. Below this zone is a large area of delicate, œdematous, fibrous tissue. This is continuous with that seen in the clefts between the hyaline, osteoid bands. It is traversed by some very long and remarkably slender trabeculæ of lamellar bone. It also contains a few small portions of membrane bone.

The fibrous tissue shows a pale matrix which does not give the staining reactions of mucin. In this there are some very fine fibrils which are stained pink by van Gieson's stain, and relatively few slender, spindle, and stellate cells—which have long protoplasmic processes. There are many capillaries and there are numerous large extravasations of red blood corpuscles. A few lymphocytes are also present. In some sections there is a small area which differs considerably from the rest. It contains a few small narrow trabeculæ of coarse fibrillar osteoid tissue and bone. On the surface of one of these there are some osteoclasts. In the surrounding tissue there are several (13 in one section) multinuclear giant cells of similar structure to the osteoclasts. Further, the spindle cells are much more numerous, smaller, and less elongated. They also vary slightly in size and shape. There are no atypical nuclei, however.

In this fibrous tissue there is a large rounded space. It is in part sharply defined, in part ill defined, being bounded by a portion of the fibrous tissue which has been destroyed by hæmorrhage. It is filled by red corpuscles with a few fibrin filaments. Serial sections show that this space communicates with the main cavity.

The tissue contains some bony trabeculæ. As mentioned above, some small trabeculæ of coarse-fibred osteoid tissue or bone were found. There are also a few very long and exceedingly slender trabeculæ of membrane bone. These extend from the upper to the lower boundary of this zone and anastomose with one another. They have a narrow core of a substance in which there are no nuclei. This substance has a marked affinity for hæmatoxylin. In sections stained with Weigert's iron-hæmatoxylin and van Gieson and differentiated for a considerable time in water, it is stained blue in contrast to the bone and osteoid tissue. It thus reacts like the remnants of hyaline cartilage in the trabeculæ of normal bone. Further, in sections treated with Twort's stain (neutral red and light green) it is stained a bright red. Control sections show that hyaline cartilage is stained bright red by Twort's stain, whilst bone and osteoid tissue are stained green. The core therefore consists of hyaline cartilage in which there are no cartilage cells. Its outline is exceedingly irregular, showing numerous bays and blunt processes. It often appears to be interrupted. Unlike the remnants of cartilage in trabeculæ of normal bone, its margins are not sharply defined. They are stained deeper than the central part and show a felt-work of short, delicate fibrils which pass into the superjacent bone. In a few places these cartilaginous strands have bone on only one side, or both sides are free from bone and in contact with the fibrous tissue. In the greater part of their extent, however, they are covered by a narrow layer of lamellar bone. The latter has an osteoid zone on which a row of osteoblasts rests. Near the upper boundary of this zone a few fragments of similar hyaline cartilage are covered by a broad layer of osteoid tissue. The latter is devoid of nuclei and resembles in structure the hyaline bands of zone No. 1.

[16] Brit. Med. Jour., Dec. 18th, 1909, p. 1751.

There is also in this situation a small mass of similar hyaline cartilage. It consists of a network of narrow irregular trabeculæ enclosing very small spaces. The edges show the same felted fibrils, and these often bridge the spaces. In the spaces there is fibrous tissue containing cells which resemble osteoblasts. This fibrous tissue is in a few places osteoid.

3. In the periphery of the above area there is a broad zone of fibrous tissue which contains many trabeculæ of lamellar and membrane bone. This zone is semicircular and bounds the area of zone No. 2 not only inferiorly but laterally.

The fibrous tissue is continuous with that of zone No. 2. Here, however, it appears less œdematous. The fibrils are slightly more distinct and the elongated spindle cells are relatively more numerous. The capillary spaces are much larger. Lymphocytes are more numerous. There are also a few myelocytes and pigment granule cells.

Some of the trabeculæ consist entirely of membrane bone. These are more numerous towards zone No. 2. The majority consist of lamellar bone and many are segmented showing several lamellar systems. The largest trabeculæ are as stout as those in a control section taken from the diaphysis of the humerus of a boy aged 11 years. Almost all, however, contain, centrally, small fragments of membrane bone. Cartilage is not present. Osteoblasts rest upon the surface of a narrow osteoid zone. Osteoclasts in lacunæ are fairly numerous.

4. Separating the above zone from the normal medulla beneath is a narrow zone in which the fibrous tissue is much denser and contains stouter collagen fibres. In it there is a large amount of pigment which gives an iron reaction when treated by the Turnbull's blue method. It also encloses collections of myelocytes. In a section stained with Weigert's elastin some elastic remnants were found which were evidently derived from destroyed vessels. This zone is slightly bowed, with its convex surface towards zone No. 3. No trabeculæ of bone cross it, but a row of trabeculæ lies upon, and parallel to, its upper surface. It is continued upwards to separate the lower lateral aspect of zone No. 3 from the marrow beneath the cortex. Here it is deeply pigmented but is very ill defined and much less dense. The connective tissue cells and fibres of this zone are continuous with the supporting tissue of the marrow in zone No. 5.

5. This zone consists of normal medulla below the abnormal tissue and on its infero-lateral aspect. The marrow is cellular with small groups of fat cells. The cells consist of myelocytes and the other constituents of normal marrow; megakaryocytes are abundant. The supporting tissue of the marrow merges with the fibrous tissue in zone No. 4. The trabeculæ are of normal appearance. They are formed of lamellar bone. They are covered by osteoblasts. The osteoid zone is very narrow.

In sections treated with Weigert-Gram's and Twort's stains no bacteria were found.

Summary of microscopic report.—The microscopic structure of the cyst may be summarised as follows. It lies in a mass of solid tissue and has no epithelial nor endothelial lining. The surrounding mass consists essentially of a delicate fibrous tissue containing fine collagen fibrils and relatively few spindle and stellate cells. There are many capillaries within it and numerous areas of hæmorrhage. Blood pigment is present, especially in its periphery. It contains considerable numbers of lymphocytes and a very few eosinophil leucocytes and plasma cells. Where this fibrous tissue bounds the cyst it contains closely packed trabeculæ of an osteoid tissue devoid of nuclei. A few of these trabeculæ are impregnated with calcium. External to this it contains a very few small trabeculæ of membrane bone or osteoid tissue, and is traversed by a few remarkably long and slender trabeculæ of lamellar bone with a core of hyaline cartilage. There is also a small group of trabeculæ of similar cartilage; these are arranged in a reticular manner and enclose a tissue which contains osteoblasts and is in places osteoid. None of the cartilage contains cells. The fibrous tissue then becomes somewhat less œdematous and contains larger capillary spaces. It now occupies a zone in which there are many trabeculæ of membrane and lamellar bone. The trabeculæ of lamellar bone almost all contain portions of membrane bone in their centres. The majority of these trabeculæ are large and stout. Finally, at the periphery of the mass is a narrow zone in which the fibrous tissue is denser. Here it contains a very large amount of blood pigment. It also contains groups of myelocytes. It is not traversed by osseous trabeculæ. Its cells and fibres merge with the supporting tissue of the marrow of the medulla. This marrow and the trabeculæ of bone within it are of absolutely normal appearance.

Active resorption of bone in the fibrotic area is evidenced by a few osteoclasts in lacunæ upon the small membranous trabeculæ in the neighbourhood of the innermost zone and the lamellar trabeculæ in the third zone. Apposition of bone is much more general; the majority of the trabeculæ show an osteoid zone covered by osteoblasts.

One small area was found in which the fibrous tissue was much more cellular and contained multinuclear giant cells.

In the fibrous tissue there is a small cyst which communicates with the main cyst. It has no epithelial lining. Its wall is in part well defined, but not bounded by trabeculæ of osteoid tissue such as are present in the margin of the main cyst. The rest of its wall is ill defined and consists of an area of the fibrous tissue which has been destroyed by hæmorrhage.

Remarks.—The relative scarcity of the cells in the fibrous tissue, their uniformity and the structure of their nuclei exclude the presence of sarcoma. The small cellular area which contains multinuclear giant cells might, if seen alone, suggest giant-cell sarcoma. But here also there is little polymorphism in the cells, and no atypical nuclei are seen. The presence of giant cells and the increased number and younger form of the connective-tissue cells are explained by the active resorption and formation of membrane bone which are seen in this area.

In its structure and in its mode of transition into the normal marrow the fibrous tissue resembles that of a myelitis rather than that of a benign neoplasm. The narrow, denser zone at its periphery has not the characteristics of a pressure capsule. It is well defined only where it separates the fibrotic area from the subjacent medulla; it is very ill defined on the lateral aspect. Further, where it is well defined, its convexity is directed towards the centre of the fibrotic area. The increased density may possibly be due to the irritation of the abundant pigment. It is more probably due to mechanical influences; either to slight lateral movement of the fibrotic area upon the subjacent medulla, or to partial or complete separation at this point. The arrangement of the trabeculæ on its superior surface and the destruction of small vessels within it are in favour of such a mechanical origin.

The general arrangement of the abnormal fibrotic area suggests a chronic inflammation with the point of maximum intensity in the situation of the cyst. The formation of the osseous trabeculæ is greater in the periphery—that is, in the third zone. Such a picture may be seen where an area of medulla has been destroyed by a known inflammatory process. But the minute histological structure affords no evidence of any specific inflammation. A few plasma cells and eosinophil leucocytes were found on careful search, but these are not present in sufficient numbers to justify a diagnosis of chronic septic inflammation. Moreover, cysts due to chronic infection by pyogenic organisms (osteitis albuminosa) have been found in the medulla of the long bones and these differ in structure markedly from this cyst. Braun,[17] for instance, described a cyst from which staphylococcus pyogenes albus was cultivated. The cyst had caused a local swelling in the tibia of a girl, aged 18 years, and had been present for several years. Its presence was not accompanied by fever. But in this case the corticalis was thickened and the cyst was lined by a whitish membrane. The microscopic structure was typical of chronic septic inflammation; the wall of the cyst consisted of granulation tissue which contained numerous fat-granule-cells and was extensively infiltrated by polymorphonuclear leucocytes. Further, diplococci were demonstrated by Gram's method. The abnormal tissue therefore appears to be a fibrosis of the marrow of inflammatory origin, but there is no evidence of any specific irritant. The structure of the trabeculæ in the third zone witnesses to the chronicity of the process. The portions of membrane bone within them show that they originated in an abnormal process of ossification. Their large size and their division into lamellar segments show that they have been present for a long time.

Hyaline cartilage is present. The extreme length of the

[17] Professor Dr. Braun: Beiträge zur Klinischen Chirurgie, Band III., 1907, S. 476, Fall 1.

strands of this cartilage and their disposition show that they are not connected with the normal endochondral ossification. But the structure has no resemblance to an ordinary enchondroma. The cartilage is either the remnant of a large mass which has been almost completely replaced by the fibrotic marrow or it has been formed by the fibrotic marrow. From the histological appearances it is impossible to decide with certainty which of these processes has occurred. The margins of the cartilage are rarely well defined; fine fibrillar brushes pass into the bone or osteoid tissue which has been deposited upon them. They have not the sharply-cut appearance which is seen in the cartilaginous remnants in normal endochondral ossification or in the ossification of ecchondroses. This indicates that the cartilage has not been eroded by the fibrous marrow. But such frayed edges might be the result of degenerative dissolution. It may be said that the histological appearances are in favour of the view that the cartilage has been formed by a metamorphosis of the fibrotic marrow analogous to that which has led to the formation of the osteoid tissue and membrane bone.

The formation of cartilage might be an accidental complication due to the healing of a fracture or infraction. But this explanation is inadequate in other cases of bone cysts in which cartilage was present. Again, cartilage has been found rarely, if ever, in cases of osteitis fibrosa (von Recklinghausen,[18] Rehn,[19] Mönckeberg,[20] Gaügele[21]) in which there has been a similar rarefaction leading to fracture of the long bones. In this connexion it may be mentioned that the structure of the wall of the recent accessory cyst suggests that the main cyst has been formed by solution of the fibrotic marrow and not by degeneration of any cartilaginous remnant or growth.

The structure of that portion of the medulla which is not involved in the fibrosis shows that no general disease of the skeleton is present. Thus the narrowness of the osteoid zone upon the trabeculæ excludes active rickets and osteomalacia.

It may therefore be concluded that the formation of the cyst is associated with a local process which is of the nature of an inflammation. This process has led to fibrosis of the marrow with destruction of old bone and the formation of recent osteoid tissue, membrane and lamellar bone. The process is of long duration. The process has also led to the formation of hyaline cartilage; or possibly the process has been provoked by the degeneration of an abnormal deposit of cartilage.

It is impossible to make a more precise conjecture as to the nature of the morbid process without first analysing the other reported cases of bone cysts, of osteitis deformans, and of osteitis fibrosa. Owing to want of space here this analysis has been reserved for publication elsewhere.

ANAPHYLAXIA IN HAY FEVER, NETTLE-RASH, AND ASTHMA.

BY G. BILLARD,

PROFESSOR TO THE MEDICAL COLLEGE OF CLERMONT-FERRAND; PHYSICIAN AT THE HÔTEL-DIEU.

IN a memoir published in conjunction with L. Maltet in the *Journal de Physiologie et de Pathologie Générale*[1] I have set forth a very ingenious theory advanced by Professor Langlois: "Hay fever is a good example of anaphylaxia so closely studied by Ch. Richet; a first attack, far from imparting immunity, renders the subjects extremely susceptible." Thus, for several years an individual is attacked by continual catarrh to which he does not attach any great importance; anaphylaxia does its work, and eventually the patient is exposed to infection and has a fit of asthma.

I wish to place special emphasis on this theory, that all persons attacked by hay fever are anaphylactised persons. I will proceed, first of all, to reproduce the observation of my co-worker, Maltet. This observation shows very clearly the successive steps in the strides of the disease from nasal catarrh to a bad attack of asthma.

M—— is asthmatic, periodically asthmatic. At first qualifying for a doctor in pharmacy, from 1894 to 1897 he suffered very frequently from nasal catarrh when handling the drugs, but he took no notice of it and never felt difficulty in breathing. During his year of military service the colds in the head disappeared, although he frequently slept amongst the hay, but in very airy spaces. M—— then passed four years at the Medical College of Lyons, and the symptoms of catarrh only appeared at rare intervals, in spite of his assiduous work at first in Professor Grola's and afterwards in Professor Lepine's laboratory.

He went, as a young practitioner, to live, in 1902, at Clermont-Ferrand in a workshop close to the house of a herbalist. After a short time frequent attacks of the catarrh appeared, then one day shortness of breath came on unexpectedly: M—— was very asthmatic.

He prescribed at first for himself with old drugs ready to hand. The attacks became more frequent, more acute. His doctor advised a season at Mont-Durant, and during this time there were no attacks, but the return to the pharmacy brought on the complaint afresh.

After visiting a specialist for nasal disorders, who cauterised, performed resection, and removed certain portions of the mucous membrane, he felt no relief; the disease lay in wait for him at his doorstep. The attacks became terrible and alarming. The patient was compelled to leave his home in order to obtain relief and a return to a normal state; he did not dare to return home. He went to Dr. Garel, who advised him to give up the pharmacy.

M—— then commenced his medical studies. He had no longer the fits of asthma, but he was always very sensitive to a large number of pollens and germs whenever he happened to be in their presence in a confined space where they were in suspension.

This observation, then, is most instructive and shows in a striking manner the progress of anaphylaxia. As a result of my own research and study in this direction for a period exceeding six years, I could bring forward a great number of similar observations, and all whom this question interests can recall identical facts in their practice or from their medical memoranda. At the present time it seems to me irrefutable that all the asthmatic symptoms of hay fever, or rather that those which began by a hay-fever cold and which have increased to fits of asthma, have been thus evolved by an anaphylaxia peculiar to pollens and germinating dust.

In the memoir previously quoted I mentioned that, as an explanation of this peculiar sensitiveness of certain subjects to pollens and germinating dust, I had adopted the hypothesis of Withehill Hinkel of Buffalo, who recognises three conditions essential to the production of hay fever: (1) A nervous temperament, hereditary or acquired; (2) a sensitiveness, or a peculiar morbid excitability of the mucous membrane, or indeed a nasal complaint; and (3) an external irritant. I now extend these three conditions to hay asthma and to ordinary asthma. After very close observation of my patients I have come to this conclusion, that the majority of subjects attacked by hay fever or asthma are persons hereditarily anaphylactic, or have during their life acquired anaphylaxia. As a result of Professor Richet's remarkable discovery, that certain poisons injected in animals are capable of altering the organisms of the latter to such an extent that they become more and more sensitive to these poisons, it would appear that a whole series of inexplicable disorders find an easy explanation if anaphylaxia is taken into consideration.

In a recent clinical lecture[2] Professor Hutinel says "that acetonæmic vomiting may be considered a sort of digestive asthma. The bilious headache represents, on the other hand, a kind of nervous asthma; eczema, a cutaneous asthma; and gout, an asthma of the joints. The common ground of arthritis brings these diverse complaints into close connexion. Thus it is common to find amongst the ancestors of asthmatic persons nervous troubles, gout, diabetes, obesity." In my opinion, all these manifestations depend on anaphylaxia.

A manifestation of anaphylaxia which in my eyes ranks prominently amongst the neuro-arthritics is nettle-rash, which is frequently observed in the course of anaphylactic accidents such as poisoning by shell-fish, by certain fruits such as strawberries, and certain medical products such as antipyrin. For some years I have been struck with the fact that it is rare for a neuro-arthritic in the course of his life not to have had nettle-rash of some sort. Not only does one discover this nettle-rash among the individuals affected, but almost always in their hereditary family antecedents.

Dr. I. N. came of ancestors suffering from arthritis in an

[1] Essais de Sérothérapie contre le Rhume des Foins et contre l'Asthme, par G. Billard et Maltet, Journal de Physiologie et de Pathologie Générale, March, 1907.

[2] Le Correspondant Médical, January, 1910.

acute form, but he only of the family had had poisonous nettle-rash. During his childhood he ate daily, and in considerable quantities, all kinds of sea fish and crustacea without any apparent change in his health, which up to then was excellent. At 18 years of age certain things happened. 1. When 18, at an evening meal, he partook of skate; at the end of the meal, left alone by the guests, he was affected with inconvenience in breathing, with a generalised form of nettle-rash, and afterwards with asphyxia; ipecacuanha was given, and a complete cure effected in one night. 2. Some months later at the evening meal he ate some mussels. At the end of the repast the same acute symptoms occurred, and the same cure was effected by an emetic. 3. When 19 years, he partook of some sea-crayfish at the evening meal. Towards 11 o'clock cutaneous nettle-rash appeared with hissing noises in the bronchial tubes. Of course, after each occurrence he gave up the incriminating food. 4. When 25 years old, one evening he was tempted by some very fine mussels. He ate one only. In the night he was attacked by a mild form of nettle-rash. 5. When 50 years of age, he ate oysters in the evening; in the night nettle-rash and hissing noises in the bronchial tubes ensued. 6. At 56 years, he ate a little red mullet from the Mediterranean, and this caused a mild fit of asthma and some irritation in the chest in the night.

Here, then, was a patient who, by means of successive nettle-rash producing reagents, was brought to an asthmatic condition. This picture, unless one is mistaken in it, resembles the notes on M. reproduced above.

If nettle-rash is really an anaphylactic manifestation we ought to find it in cases of asthmatic patients. There does not appear a doubt that nettle-rash is a manifestation of anaphylaxia, as the works of Bruck witness.[3]

It is known that Wolf Eisner has expressed the hypothesis that nettle-rash is an anaphylactic phenomenon connected with the foreign albumins in the organism. In order to prove this theory the author has carried out research work to see if substances which are known to excite nettle-rash in man are capable of giving rise to anaphylaxia in animals, such as rabbits and guinea-pigs, which have been injected previously with the serum of the pig or the extract from the muscle of the crab. Now these animals present, after renewed injections from these substances, typical phenomena of anaphylaxia; again, the injection of the serum from these anaphylacticised animals into other animals was found to render them hyper-sensitive.

The author has been able to establish, moreover, that in the case of man alimentary nettle-rash was an anaphylactic reaction. A young man could not for two years after having eaten a pork sausage, which produced morbid effects, partake of any pig meat without suffering immediately from an extended eruption of nettle-rash. Now the injection of the serum from this man into a guinea-pig excited immediately an extremely clear anaphylaxia with regard to the pig's serum.

It is generally known that the treatment introduced by Dr. Rowland (of East Corinth), who recommended the injection of anti-diphtheric serum as an antidote to hay-fever and obtained at first excellent results, has had to be given up on account of very serious, and sometimes fatal, accidents of anaphylaxia amongst those predisposed. I have, on my part, observed a nettle-rash and grave anaphylactic accidents in the case of a young child (asthmatically) predisposed, following an injection of Roux's serum in the course of diphtheria.

What are the substances which can cause anaphylaxia? I cannot do better than refer to the work of Armand-Deville,[4] from which I extract the following law:—

> There exist a certain number of organic substances which, introduced for the first time into the organism, in innocuous doses, have the property of producing in the organism, after a fixed period of incubation, anaphylaxia—that is, an extreme sensitiveness to minimum doses of the same substance, which produce no trouble in an organism not so treated. This anaphylactic condition appears to be connected with the development in the organism of a body, or of a special property which exists, amongst others, in the serum of the blood, since by introduction of this serum into another individual of the same species this person is immediately plunged into a state of anaphylaxia.

These substances, of organic origin, are derived either from the animal or the vegetable kingdom. They are introduced usually by the digestive tract. Others, on the contrary, penetrate through the respiratory tract or through the mucous membranes of the eye.[5] It is especially these last which interest us here. The toxic albumins, pollens and germs, which reach the mucous membranes of the eye or of the upper respiratory tracts cause there what I have called up to the present nettle-rash in the upper respiratory tracts.

In the memoirs published in conjunction with Maltet, at first in the *Journal de Physiologie et de Pathologie Générale*, then in the *Gazette des Hôpitaux*,[6] I have said that essential asthma, irregular in its recurrences, can be excited by the toxic albumins, pollens and germs. I am obliged to recognise to-day that these last toxic substances are not the only ones to provoke the fits of asthma, and with certain of my patients I have seen these appear as a sequel of indigestion from high game, and also following the indigestion from sea fish, crustacea, &c. And thus, as the data I published quite recently indicate, very slight proportions of substances introduced into the stomach are able to cause the attacks. I am convinced that it is for this reason that diet-tables have been established empirically at the spas where neuro-arthritics are treated. These diet-tables have, in effect, as their aim the suppression, as far as is possible, of anaphylactic substances. Now, even there individual susceptibilities are not taken into account, so that a patient who would never have an asthmatic attack in eating sausage would show symptoms of such an attack if he had taken an oyster. There are, I believe, few persons who have not observed for themselves that certain foods and certain substances do not "pass," causing various forms of indigestion, regarded as trivial, which are in reality nothing less than anaphylactic manifestations of the organism. Moreover, certain poisonous foods, and in particular the poisons conveyed by certain kinds of fish, by crustacea or molluscs, and even the nettle-rash produced by strawberries,—all these, it seems, can legitimately be placed under the phenomena of anaphylaxia, although it has not been possible, experimentally, to obtain the anaphylaxia with serum. It is, however, in consequence of the possibility of this process that Hutinel has been led to hold the view that intolerance to certain nutriments, both in the maternal milk and in cow's milk, is a true manifestation of anaphylaxia in milk. Again, we are certainly entitled to place in the category of anaphylactic reactions, although the intimate mechanism of them may be slightly different, the phenomena that the inoculation of tuberculin produces in a tuberculous subject.

Everybody is aware to-day that in hereditary neuro-arthritis different conditions are transmitted which constitute varying manifestations of neuro-arthritis. It is known, for instance, that a corpulent person will have a gouty son; that this gouty son may have an asthmatic or diabetic son, or one subject to gravel, &c. In a family that I attended for four years in the south I was able to state the following facts: a grandfather with thickened arteries and chronically rheumatic; a grandmother literally poisoned every time she ate sea fish or crustacea, having, moreover, eczema in the hands every time she touched primroses, the cause of which was for long unknown; a daughter, cholo-lithic; grandsons, the first asthmatic, the second tuberculous, the third attacked by manifestations of poisoning following on indigestion from sausage and oysters.

From the whole of the facts that I have cited above I am able to conclude that neuro-arthritics, and especially asthmatics and those predisposed to hay fever, are victims to anaphylaxia, either acquired or hereditary.

[4] L'Anaphylaxie, Masson and Co., Paris, 1910.

[5] I would add, indeed, that certain of these penetrate through the skin. Certain neuro-arthritics contract eczema in contact with primroses, chrysanthemums, &c.

[6] Billard et Maltet: Gazette des Hôpitaux, 1909, No. 52, p. 651.

TUNBRIDGE WELLS GENERAL HOSPITAL.—Sir David Salomons, Bart., has just presented to the Tunbridge Wells General Hospital some radium, an installation of the Roentgen rays, and a Finsen lamp. The radium will remain in the custody of the hospital authorities, but will be available for private practitioners on payment of a small fee. The Roentgen rays apparatus will amplify that at present in use. The hospital has previously benefited by gifts from Sir David Salomons.

THREE CASES OF THROMBOSIS OF THE LATERAL SINUS

BY J. WALKER WOOD, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.,

FORMERLY HOUSE SURGEON, CENTRAL LONDON THROAT AND EAR HOSPITAL.

THE following three cases occurred during my recent term of office at the Central London Throat and Ear Hospital, and were all under the care of Dr. Percy Jakins, to whom I am indebted for permission to publish them.

Thrombosis of the lateral sinus is one of the complications of middle-ear suppuration that practitioners always have to be on the look-out for. It may show itself as a perfectly clear clinical picture presenting no great difficulties of diagnosis, or, again, should it be masked by signs and symptoms of some other intracranial complication, such as meningitis or brain abscess, it may be a very difficult task to decide the exact lesion with which you have to deal. Haseler's figures show that in 81,684 cases of chronic middle-ear suppuration 116 deaths took place from intracranial complications, and of these 48 were due to thrombosis, 40 to meningitis, and 28 to brain abscess. Figures obtained from the hospitals of London by Pitt show an almost exactly similar proportion. Thus it is evident that thrombosis of the lateral sinus is one of the most frequent, if not the most frequent, complications of a suppurating ear. When the prevalence of chronic suppurative catarrh and the proximity of the lateral sinus to the mastoid antrum (for the antrum is always involved in chronic suppurative catarrh, if not the prime cause of persistence of suppuration in the ear) are considered—it may be the sinus forming one of the antral walls—it is surprising that thrombosis is not more common than it is. I can recall several cases when on opening the mastoid the sinus was found lying bare in the posterior wall of the antrum, covered with granulations and exposed to absolute direct infection. When thrombosis does take place the infection is brought about more frequently through intercommunicating venous channels than by direct extension. This is quite easily understood when the great resisting power of the dura is considered—a resisting power much greater than that of bone; the presence of granulations on the dura in some cases is in reality an additional protection against infection of the sinus.

In all cases of chronic middle-ear suppuration the surgeon ought ever to be on the *qui vive* for symptoms which indicate intracranial trouble. Patients should be warned of the dangers which they run; urgent symptoms should be explained to them, as headache, vomiting, giddiness, shivering fits, mastoid pain, &c. In addition they ought to be impressed with the necessity of immediately reporting themselves to the aural surgeon should one or all of these symptoms become evident. The onset and symptoms of thrombosis are more easily explained by a consideration of the following cases.

CASE 1.—The patient, a male, aged 14 years, was on Sept. 6th, 1909, admitted to the Central London Throat and Ear Hospital with a history of a discharge from the right ear of three months' duration. The discharge ceased suddenly a week previously to admission, and two days later the lad complained of severe pain in the head. The pain was located principally behind the right ear, and was very severe and constant. Since the discharge ceased the patient had had several rigors. There was marked tenderness in the occipital region over the site of the mastoid emissary vein (Griesinger's symptom) and along the line of the internal jugular vein. The head was bent over on to the right shoulder and supported with the patient's right hand. There was no mastoid swelling or tenderness. The temperature was 100·8° F., and the pulse 120, small and weak. Shortly after admission the patient had a severe rigor, the temperature rising to 104°. The tongue was coated and furred. The pupils were equal and active and the discs normal. There was no nystagmus, nor was there rombergism, and the reflexes were normal. Dynamometer: right hand, 50; left, 40. There was no vomiting or nausea, and consciousness was clear and unimpaired. The right meatus was full of inspissated pus and no view of membrane was obtained. A diagnosis was made of thrombosis of the lateral sinus.

Operation.—On Sept. 6th the right mastoid was exposed by the usual incision behind the ear. The mastoid cells were opened and were found to contain pus. The antrum also contained pus and cholesteatoma. The bridge and ossicles were removed. The lateral sinus was next exposed, and as soon as the bony wall was broken through pus welled up into the wound (peri-sinus abscess). The sinus contained a large whitish clot, very offensive, not broken down but firmly adherent. The clot was partially removed with spoon and curette (but not until fluid blood was reached), and the sinus was plugged with iodoform gauze. At this point there was troublesome hæmorrhage from the mastoid emissary vein. The upper flap, which had been cut previously, was stitched into place, a large rubber tube was inserted in the meatus and partial closing of the post-auricular wound completed the operation.

A pathological report of the pus by Dr. Wyatt Wingrave stated that it contained almost every variety of known organisms with the exception of the tubercle bacillus, the predominating ones being the streptococcus, the staphylococcus, the bacillus proteus vulgaris, and the bacillus pyogenes fœtidus.

On Sept. 7th the patient's condition had improved slightly. The temperature was subnormal, and the pulse was 78 and very irregular. Vomiting and rigors were absent. There was slight head retraction. Kernig's sign was present but not marked. When the wound was dressed the discharge was principally blood-stained serum. On the 8th the patient's general condition had greatly improved and the pulse was more regular. There was a slight rise of temperature at 2 P.M., but no rigor. The head retraction had disappeared. The urine contained a trace of albumin. The wound was dressed. The discharge was very fœtid, and on this account a dressing of chlorinated soda was used; the plug in the lateral sinus was also changed. On the 9th the general condition remained good, the pulse being 86 and the temperature 98°. The tongue was coated, but there was no sickness or nausea, and no rigors or headache. There was now no pain on pressure over the internal jugular vein. From the 10th to the 21st there was steady convalescence. The wound was dressed daily, being sponged out with hydrogen peroxide and plugged with plain sterile gauze. The patient was allowed to get up on this day. On Oct. 11th he was sent home. The wound had healed, but there was a slight discharge through the meatal canal. On March 7th, 1910, the discharge had quite ceased and the hearing was good.

This was a fairly typical case of thrombosis of the lateral sinus. The following are the main points of importance:—(1) Cessation of discharge; (2) sudden onset of pain behind the ear; (3) tenderness along the internal jugular vein; (4) shivering (rigors); (5) Griesinger's symptom (tenderness and slight œdema over the site of the emissary vein, although no tenderness or swelling over the mastoid antrum); (6) the discs normal; and (7) consciousness unimpaired.

The next case illustrates well the difficulties of diagnosis. From the history, the examination of the patient, and the lumbar puncture, a diagnosis of meningitis was quite justified.

CASE 2.—The patient, a married woman, aged 28 years, was sent by Dr. J. Read Pooler to the Central London Throat and Ear Hospital to be placed under the care of Dr. Percy Jakins on Dec. 28th, 1909. There had been discharge from the left ear all her life, increasing during the last three weeks. A week before admission there had been a sudden onset of high temperature, ranging from 101° to 103° F., accompanied by a dull, drowsy condition, with head retraction and severe frontal and occipital headache. There was occipital pain radiating down the spine, with marked tenderness in the region of the occiput and over the site of the mastoid emissary vein on the left side. The slightest movement of the head caused severe pain. The patient could be roused to answer a question, but would immediately lapse into a dull, drowsy condition. The face was alternately flushed and pale. The temperature was 100° and the pulse was 100 and irregular. There was obstructive deafness. The meatus was full of inspissated pus; no view of membrane obtained. The tongue was coated and furred. There was no paresis of the ocular muscles or nystagmus, and the pupils reacted to light and accommodation. Slight optic neuritis was present on both sides. The knee-jerks were sluggish, the left one being almost absent. There was ankle clonus on both sides, most marked on the left side. Dorsiflexion on both sides; Kernig's sign present. Lumbar puncture was performed, and 15 cubic centimetres of fluid were

extracted under low pressure. Cells present included polymorphonuclear leucocytes 80 per cent., lymphocytes 20 per cent. Bacteria present were bacillus proteus vulgaris, bacillus pyogenes fœtidus. A culture from the cerebro-spinal fluid showed the same bacteria. An examination of the aural discharge revealed the presence of the bacillus proteus vulgaris, the bacillus pyogenes fœtidus, and staphylococci. There was no sickness, or rigors, or giddiness. A diagnosis of meningitis was made, and it was decided to explore the mastoid.

Operation.—On Dec. 29th the radical mastoid operation was performed by Dr. Percy Jakins. The bridge contained a large cell which was full of pus. A large quantity of pus was also found in the antrum. The lateral sinus was completely thrombosed, and an abscess was found between it and the bone, communicating with an extra-dural abscess in the posterior fossa. Another extra-dural abscess was found above the tegmen antri, which was carious. The dura of the middle and posterior fossæ was carefully examined, but no opening was found. In the course of the operation the external semicircular canal was obliterated. The wound being very fœtid it was dressed with chlorinated soda and hydrogen peroxide, the post-auricular wound being plugged and left open. Towards the end of the operation, whilst on the operating-table, the patient had a severe rigor. On the 30th another severe rigor was experienced and the temperature rose to 105°. The patient was very dull and drowsy and the pulse and respirations were rapid. On Jan. 1st, 1910, the temperature was somewhat pyæmic in type. Lumbar puncture was performed, but no fluid could be got out. On the 3rd the patient's condition was about the same. She could be roused to answer a question, but otherwise she remained in a semi-comatose condition. She had less pain than on admission, and the deafness was less marked. There was a tendency to left-sided facial paralysis. The wound, in spite of daily dressings, was still very fœtid, and the tendency of the temperature was to go up. On the 4th the pus from the wound was examined and was found to contain staphylococci, streptococci, the bacillus proteus vulgaris, and the bacillus pyogenes fœtidus. The patient's general condition showed slight improvement. The temperature varied from 100° to 101°. On the 5th the general condition was about the same. The patient expressed herself as feeling much better. The temperature varied, but the tendency was to keep up. On the 6th the general condition was not so good. The patient complained of headaches and was much duller, and had slight head retraction. The discs were examined again, and the edges were found to be very indistinct. There was marked engorgement of the veins, especially in the right eye; the temperature was still up. On the 15th the temperature gradually became normal and then sub-normal, the pulse remaining rapid. Consciousness became quite clear and the patient's condition was greatly improved. The wound was granulating well, but was discharging freely. On the 17th the temperature was subnormal, with a rapid pulse. The tendency to left-sided facial paralysis was more marked. There were paresis of the left external rectus and marked ankle-clonus, especially on the left side. The left knee-jerk was more active than the right. The left-hand grip was weaker than the right. Giddiness was experienced on sitting up in bed and was rotatory in type, objects appearing to go to the right. There was slight spontaneous nystagmus to the right side. Associated movements could be performed as well on the left as on the right side. There was extreme somnolence, but the patient could always be roused. On the 23rd the patient remained in the same condition, with a subnormal temperature and a rapid pulse, and she complained of headache. The reflexes and the nystagmus were as on the 17th. The patient had vomited twice. The amount of discharge from the wound varied—one dressing would be saturated with discharge, while another would be quite dry. On the 24th the headache had become very severe. Otherwise the patient's condition was unaltered. The giddiness was much less. On the 25th the headache was very severe and was referred principally to the frontal and occipital regions. The vomiting continued. The patient was very dull and sleepy, with a temperature of 97·8° and a pulse-rate of 100. The reflexes were the same as a week ago. An examination of the optic discs revealed a large flame-shaped hæmorrhage on the right side. On account of the headache and the vomiting, and the state of the pulse and temperature, Dr. Jakins decided to explore the temporo-sphenoidal lobe. On the 27th a second operation was performed. The old wound was opened up, an incision was carried up vertically behind the ear, and the periosteum was elevated. A trephine opening was made half an inch directly above the meatus and the middle fossa was opened. The meninges appeared to be quite normal. The dura was incised. The temporo-sphenoidal lobe was explored with the "pus-seeker," but no abscess was found. A small fistula was found in the tegmen antri; this was well opened up. On the 28th, following upon the operation, the patient was very dull and collapsed, the temperature being 96° and the pulse 40. She was semi-conscious, cold, and in a condition of extreme shock, with feeble, irregular pulse and dilated pupils. Brandy, strychnine hypodermically, hot water bottles, and hot saline enemata were freely used. She remained in this condition for two days, when, suddenly becoming fully conscious, alert, and brisk, she desired to sit up in bed to read, and was able to answer any questions intelligently. The sudden change in the condition of the patient was associated with an increased discharge of pus from the mastoid wound. The slight paresis of the face and eye had improved, and the wound was granulating well. On the 31st Dr. Purves Stewart kindly saw the case with Dr. Jakins. He could find no local lesion, only general meningitis. The wound granulated well and the patient made an uninterrupted recovery, leaving the hospital with the wound closed on Feb. 28th, the facial and ocular paralyses having entirely disappeared. When seen on March 12th the patient appeared to be in splendid condition. She had been staying at Bournemouth for 14 days and had not had, she said, a headache since the last operation.

How far the diagnosis was at fault will be readily seen from the subsequent history of the case as narrated above. Meningitis was present, but in addition there was a completely thrombosed sinus, a peri-sinous abscess and an extra-dural abscess. The points in favour of meningitis were: (1) continuous high fever and no rigors until after the operation; (2) the dull and drowsy condition of the patient; (3) the head retraction with pain on movement; (4) the lumbar puncture; and (5) optic neuritis.

During the further progress of the case several points suggested either an extra-dural abscess or a brain abscess. They were: sub-normal temperature and pulse; the ocular paresis; the condition of the reflexes; headache and vomiting; hæmorrhage into the left optic disc; and the variable amount of discharge from the mastoid wound. The giddiness and nystagmus were most likely due to a localised labyrinthitis caused by an injury to the labyrinth during the first operation. The absence of rigors with a totally blocked sinus is worthy of note.

The last case is a further instance of diagnostic difficulties.

CASE 3.—The patient, a male, aged 4½ years, was sent to hospital by Dr. G. Thomson of Ealing. The boy had been operated upon at another hospital for tonsils and adenoids. Fourteen days later the maxillary glands on the right side of the neck commenced to swell and eventually they broke down, forming an abscess, which was opened. During the following week both ears began to discharge. The patient was on June 1st, 1909, admitted to the Central London Throat and Ear Hospital under the care of Dr. Jakins. He was evidently in great pain and was extremely restless. The face was drawn and pinched, and the cheeks were flushed. The temperature was 100° F., and the pulse was 120 and irregular. There was profuse discharge from both ears, with some tenderness of the right mastoid, but no swelling or redness. A large mass of broken down glands in the neck was still discharging freely. There had been no rigors or sickness. Consciousness was quite clear, but the child complained of pain in and behind the right ear.

Operation.—Cortical mastoid right. A post-auricular incision was carried down into the neck to include the old incision made for the abscess. The bone was soft and carious. The antrum when opened was found to contain pus under pressure; the lateral sinus was exposed and was found to be completely thrombosed with granulations all round. As the thrombus consisted of a healthy clot it was not removed, nor were the granulations over the sinus curetted. The bridge was not removed. The wound in the neck was laid freely open and the glands were well scraped. The whole wound was then plugged and left open. On June 2nd the temperature was rising, and the patient was still very restless and in pain. His

general condition remained the same. The wound when dressed discharged freely. Ankle clonus was present on both sides. On the 3rd the temperature was oscillating and the pulse was rapid and irregular, but there were no rigors. The discs were normal. On the 10th there were no rigors but great oscillations of temperature, an evening rise to 103° or more, falling in the morning to normal. The patient complained of headache and of pain in the left ear, but there was no sickness. The chest was examined with a negative result. On the 12th a second operation was performed, Dr. Jakins deciding to explore the left mastoid. The usual incision behind the ear was made and the bone was exposed. The antrum was opened and was found to contain pus under pressure, the surrounding bone being soft and carious and easily removable with a sharp spoon. The lateral sinus was not exposed. The wound was plugged and left open. There was a rise of temperature in the evening to 104°. On the 13th the temperature was still remittent in type but there were no rigors. There was slight head retraction. The patient complained greatly of headache, which was principally occipital. There was no impairment of consciousness. On the foregoing symptoms it was decided to investigate the condition of both sinuses. A third operation was performed on the 14th. The sinus of the right side was first examined and was found to be perfectly patent, although only a fortnight previously it was completely thrombosed. After plugging the right wound the left sinus was investigated, and as its wall appeared to be healthy and as it pulsated freely it was not interfered with. There was great sickness for several hours after the operation with subnormal temperature and pulse. On the 16th the sickness continued, but with no rigors, and there were profuse and marked perspirations, which were limited to the head. Tache cérébrale was well marked; Kernig's sign was present. Ankle clonus was present on the left side. The knee-jerks were inactive and the urine contained a trace of albumin. The child was perfectly conscious and bright. From the 17th to the 27th the temperature continued to oscillate, the oscillations gradually getting less. The lungs were again examined with negative results. The temperature slowly sank to normal. On July 1st the temperature was normal and both wounds had practically healed. The patient now returned home. When seen on Dec. 28th the boy was found to have gained greatly in weight and the hearing on both sides was normal. He looked the picture of health.

The principal points here are: (1) the remittent temperature with free perspiration, but absence of rigors; (2) the headache and sickness; (3) the absence of optic neuritis; (4) the presence of Kernig's sign, but no symptom of meningitis beyond this; and (5) the absence of Griesinger's symptom.

In conclusion, I should like to point out that in none of these cases was the internal jugular vein tied. Should rigors continue after opening the lateral sinus and the removal of clot, whether septic or not, then, and not before, is the time to ligature the vein.

Devonshire-street, W.

THE TREATMENT OF CHOLERA ASIATICA WITH AN ANTI-ENDOTOXIC SERUM.

BY R. TANNER HEWLETT, M.D. LOND., F.R.C.P. LOND., D.P.H.,

PROFESSOR OF GENERAL PATHOLOGY AND BACTERIOLOGY IN KING'S COLLEGE, LONDON; AND LECTURER ON BACTERIOLOGY, LONDON SCHOOL OF TROPICAL MEDICINE.

VARIOUS attempts have been made to prepare an anti-cholera serum for the treatment of cholera asiatica. Under ordinary conditions the cholera vibrio produces little or no toxin, and an anti-microbic serum prepared by immunisation with cultures has been found to be of no practical value.

Some years ago Metchnikoff, Roux, and Salimbeni [1] found that by cultivating the cholera vibrio in a medium consisting of a gelatine-salt-peptone mixture a feeble extracellular toxin is formed. With this toxin horses were immunised and the serum obtained was proved to possess immunising and curative properties experimentally when tested on young suckling rabbits which were found to be susceptible to infection with the cholera vibrio. In the epidemic of cholera in Russia last year Salimbeni [2] employed this serum and considers that it is undoubtedly of value. The dose was 50–100 c.c. administered intravenously in salt solution (150–500 c.c.).

Bran and Denier [3] also obtained a cholera toxin by the use of a medium consisting of horse serum with an addition of 10 per cent. defibrinated horse blood.

The late Dr. Allan Macfadyen [4] found that by the trituration of cholera cultures in the presence of liquid air the intracellular cholera juice or "cholera endotoxin" possessed decided toxic properties and by the immunisation of animals an anti-endotoxic serum was obtained which possessed considerable protective power as well as agglutinative and bacteriolytic properties. Through the kindness of Mr. Wellcome, I was able last year, at the Wellcome Physiological Research Laboratories, to immunise a horse by the Macfadyen method with cholera endotoxin prepared by the trituration of virulent cholera cultures obtained through Dr. Haffkine from India.

This anti-endotoxic serum experimentally possessed considerable protective and curative powers tested on guinea-pigs. Thus 0·0001 c.c. and 0·5 c.c. of serum protected against 10 and 50 lethal doses respectively of living cholera culture injected simultaneously intraperitoneally into guinea-pigs. Curatively 1 c.c. of the serum saved the life of a guinea-pig inoculated intraperitoneally with four lethal doses of living cholera culture six and a half hours previously.

Through the kindness and interest of Madame Sieber, of the Imperial Institute of Experimental Medicine at St. Petersburg, a trial of this serum was made on nine cases of cholera which occurred during the epidemic of last year in Russia. The patients were in the Obuchar Hospital, St. Petersburg, under the care of Dr. Stühlern, and I am indebted to him for notes of the cases and for permission to publish them. The following is a record of the cases (a verbatim translation of Dr. Stühlern's notes):—

CASE 1.—Cabinet-maker, alcoholic subject, aged 40 years. Suffered from premonitory symptoms for a fortnight, then acute onset, with cramps, pulsus parvus, and cyanosis. *First infusion*, 24 hours after the commencement of the attack. 3 litres of 0·7 per cent. salt solution with 50 c.c. of serum given intravenously (42° C.), together with 25 c.c. of serum subcutaneously. *Second infusion*, 24 hours after the first infusion. 200 c.c. of salt solution with 25 c.c. of serum, subcutaneously. *Third infusion*, 24 hours after the second infusion. 300 c.c. of salt solution with 25 c.c. of serum subcutaneously. The first infusion produced decided improvement. The patient recovered.

CASE 2.—Goldsmith, alcoholic subject, aged 48 years. Acute onset, with pulsus parvus, vox choleraica, cramps, and cyanosis. *First infusion*, 18 hours after the commencement of the attack. 3 litres of salt solution with 50 c.c. of serum intravenously, together with 200 c.c. of salt solution with 25 c.c. of serum subcutaneously. *Second infusion*, six hours after the first infusion. 2·5 litres of salt solution with 25 c.c. of serum intravenously. *Third infusion* (time not stated). 300 c.c. of salt solution with 25 c.c. of serum subcutaneously. *Fourth infusion* (time not stated). 2 litres of salt solution with 25 c.c. of serum intravenously. The patient passed into a comatose typhoid condition, developed facial erysipelas, and died on the sixth day of the disease.

CASE 3.—Agricultural labourer (*Erdarbeiter*), aged 28 years. Acute onset, pulseless, with cyanosis, vox choleraica, and cramps. *First infusion*, 20 hours after the commencement of the attack. 3 litres of salt solution with 50 c.c. of serum intravenously, together with 100 c.c. of salt solution with 25 c.c. of serum subcutaneously. *Second infusion*, six hours after the first infusion. 2·5 litres of salt solution with 50 c.c of serum intravenously. *Third infusion* (time not stated). 150 c.c. of salt solution with 25 c.c. of serum subcutaneously. The patient recovered.

CASE 4.—Cabinet-maker, aged 33 years. After premonitory diarrhœa lasting for 48 hours the cholera attack commenced, with cyanosis and small pulse. *First infusion*, 20 hours after the commencement of the attack. 2·5 litres of salt solution with 50 c.c. of serum intravenously, together with 150 c.c. of salt solution with 25 c.c. of serum subcutaneously (hæmorrhagic fæces). *Second infusion* (time not stated). 3 litres of salt solution with caffeine (*no serum*) intravenously. The patient died on the seventh day of the disease. Diphtheritic colitis was found post mortem.

CASE 5.—Waiter, aged 26 years. Cholera acutissima. *First infusion*, eight hours after the commencement of the attack. 3 litres of salt solution with 25 c.c. of serum intravenously, together with 25 c.c. of serum subcutaneously. *Second infusion*, seven hours after the first infusion. 3 litres of salt solution with 25 c.c. of serum intravenously, together with 25 c.c. of serum subcutaneously. *Third infusion*, 12 hours after the second infusion. 2·5 litres of salt solution with caffeine (*no serum*) intravenously. *Fourth infusion*, 12 hours after the third infusion. 2 litres of salt solution with 25 c.c. of serum intravenously, together with 25 c.c. of serum subcutaneously. The patient died (time not stated). Hæmorrhagic enteritis was present.

CASE 6.—Labourer, aged 20 years. The attack commenced 12 hours after premonitory symptoms. The patient was pulseless at the commencement of the treatment. *First infusion*, 12 hours after the commencement of the attack. 3 litres of salt solution with 25 c.c. of serum intravenously, together with 25 c.c. of serum subcutaneously. *Second infusion* (time not stated). 3 litres of salt solution with 25 c.c.

of serum intravenously, together with 25 c.c. of serum subcutaneously. *Third infusion* (time not stated). 3 litres of salt solution (*no serum*) intravenously. The patient recovered without "typhoidal" symptoms.

CASE 7.—Shoemaker, aged 15 years. The treatment was commenced six hours after the beginning of the attack. *Infusion*, six hours after the commencement of the attack. 2 litres of salt solution with 25 c.c. of serum intravenously, together with 25 c.c. of serum subcutaneously. The patient made an uncomplicated (*glatte*) and speedy recovery.

CASE 8.—Tradesman (*Händler*), aged 16 years. At the commencement of the treatment the patient was pulseless. *First infusion*, 24 hours after the commencement of the attack. 2 litres of salt solution with 25 c.c. of serum intravenously, together with 25 c.c. of serum subcutaneously. *Second infusion*, seven hours after the first infusion. 1 litre of salt solution with 25 c.c. of serum intravenously. *Third infusion*, 12 hours after the second infusion. 25 c.c. of serum subcutaneously. The patient made an uncomplicated and speedy recovery.

CASE 9.—Master shoemaker, alcoholic subject, aged 43 years. Cholera acutissima. At the commencement of the treatment the patient was pulseless. *First infusion*, 12 hours after the commencement of the attack. 3 litres of salt solution with 25 c.c. of serum intravenously, together with 20 c.c. of serum subcutaneously. *Second infusion*, six hours after the first infusion. 1 5 litres of salt solution, with 25 c c. of serum intravenously. *Third infusion*, eight hours after the second infusion. 2 litres of salt solution with 25 c.c. of serum intravenously, together with 25 c.c. of serum subcutaneously. The patient died on the third day of the disease.

It will thus be seen that of the nine cases four died and five recovered. The number is too small to base any conclusion as to the value of the serum, but it seems worthy of more extended trial. It will be noted that not more than 75 c.c. of serum was given at one time. This was because the serum contained 0·3 per cent. of trikresol, and Dr. Stühlern feared that the preservative might give rise to toxic symptoms if larger doses of the serum were given. The dose employed by Salimbeni was 50–100 c.c., and one would like to see a similar dosage of the anti-endotoxic serum employed.

King's College, London.

THE ACTION OF CHLORINE UPON WATER CONTAINING THE CHOLERA VIBRIO.

BY H. W. HARDING, M.D. LOND., D.P.H.,
ASSISTANT MEDICAL OFFICER, BOROUGH AND PORT OF YARMOUTH.

AT the suggestion of Dr. J. C. Thresh and under his direct supervision I have carried out in the public health laboratories at the London Hospital Medical College a series of experiments to ascertain whether the cholera vibrio was as susceptible to the action of chlorine as Dr. Thresh has shown the bacillus coli and the bacillus typhosus to be.

The results of these experiments, which have extended over a period of more than three months, are embodied in the subjoined table and require but little explanation. In each case one or two drops of a 24 hours' broth culture of the cholera vibrio were added to 1 litre of the water used. The requisite quantity of solution of chlorine was then added, and at definite intervals of time 1 c.c. of the solution was used for making an agar plate, and 100 c.c. were poured into a flask containing 11 c c. of a concentrated peptone salt solution. If any turbidity occurred in this broth within 48 hours it is indicated by the first + sign in the appropriate columns in the table. Subcultures were then made, sometimes a second and a third, in order to ascertain whether the cholera vibrio were present. If present it is indicated by the second + sign. This portion of the investigation was more difficult than had been anticipated, since the very dilute chlorine solution fails to kill certain spore-bearing organisms which grow with great rapidity in peptone water and produce a pellicle. Their presence also prevents the characteristic cholera-red production, but under the microscope they are readily distinguished from the cholera vibrio. Where any growth occurred upon the agar plates, these were used for inoculating gelatin and peptone solution. In no instance was the vibrio obtained from such a plate, even when 10,000 or more had been added to each cubic centimetre of the water. In about half the experiments a filtered cholera broth was used; in the others the broth was unfiltered.

Some experiments made by Dr. Thresh appeared to show that except in waters of a high degree of organic purity, 1 part of chlorine in 2,000,000 of water was not to be depended upon to destroy the cholera vibrio, but that 1 part per 1,000,000 seemed to be effective in ordinary waters. For this reason smaller quantities than 1 per 1,000,000 were rarely used. The results were not positive in all cases; it will be observed that in four instances in which 1 part per 1,000,000 of chlorine was used the cholera vibrio was recovered from 100 c.c. of the treated water, and in one of these cases it was found in the sample which had been in contact with the chlorine for 30 minutes, whereas it could not be found in the 10 and 20 minute samples from the same flask; these isolated instances were probably associated with the introduction of portion of the pellicle from the broth culture, for in that particular case in which the three flasks remained

infected, and in that case only, the culture was added by means of the platinum loop, to which the pellicle readily adheres. Disregarding this and recognising the fact that no potable water is ever likely to contain more than a small fraction of the number of vibrios introduced into the waters examined, I conclude that most waters, if treated with 1 part of chlorine per 1,000,000 for 15 minutes, would be free from the cholera vibrio. Where water contains so much organic matter as to consume this amount of chlorine, then more will be needed, sufficient to oxidise the organic matter, and leave 0·5 to 1 part of chlorine available for sterilising purposes.

The addition of a little sodium bisulphite, or of sodium thiosulphate, instantly destroys the excess of chlorine, but in most cases it would probably be preferable to remove this excess by filtering through iron filings, or, better still, agitating with iron filings and then passing the water through some kind of filter to remove the trace of oxide of iron formed and any suspended organic matter contained in the water.

Yarmouth.

NEW EDITION OF THE RUSSIAN PHARMACOPŒIA.—The Russian Medical Council has issued a new (6th) edition of the Russian Pharmacopœia, which is to be the governing work for pharmacists, medical establishments, and medical men in European Russia from Dec. 1st (14th) next, and in the Siberian governments and in the Caucasus from Jan. 1st (14th), 1911.—The *Gazette* of the Russian Distillers' Association says that the Russian Medical Council is examining the question of freeing from excise spirits required in medicines. It is shown that Russian pharmaceutical factories use but little alcohol. But there is a very large importation of medical preparations from abroad, where they are made with "excise free" spirit. Now in Russia, owing to the heavy excise on alcohol, many pharmaceutical products are made up with wood spirit, which is very injurious to health.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

PATHOLOGICAL SECTION.

Presidential Address.

A MEETING of this section was held on Oct. 18th, Dr. F. W. MOTT, the President, being in the chair. Dr. Mott opened the session by a demonstration and address upon the Comparative Neuro-pathology of Human Trypanosomiasis and Syphilis. He referred to the close biological relationship of trypanosome and spirochæta infection: the primary sore at the point of inoculation, the period of incubation, the local gland enlargement followed by a general infection first of the lymph stream, then of the blood associated with erythematous rashes due to migration of the parasites, fever, and constitutional disturbances. Dr. Mott then referred to the mode of transmission of human trypanosomiasis and the researches of Kleine, confirmed by Bruce, concerning the glossina palpalis and the multiplication of the parasite in the gut of the fly, so that it seems there is not only a specific trypanosome, T. gambiense, but a specific fly, the glossina palpalis. The mal de coit or dourine of horses was next alluded to as showing that a trypanosome—the T. equiperdum—had acquired a habit of multiplying in the mucus of the mucous orifices, and so perpetuating the species by transmission from one animal to another by coitus. He hinted at the possibility that the spirochæta pallida might have once been conveyed by a biting insect (we know the spirochæta of tick fever is), but, like the T. equiperdum, it had acquired a new mode of transmission and thus of perpetuating the species. The affections of the nervous system produced by human trypanosomiasis and syphilis are especially interesting, for they present many points of similarity in their clinical symptoms and morbid histological changes; moreover, it is known that the drugs which can avert affections of the nervous system in the one disease, syphilis, can avert in rare circumstances the other disease. The first most striking point in human trypanosomiasis (and he used this term instead of sleeping sickness, which he said should be abolished) is the fact that on the one hand practically all cases of human trypanosomiasis, whether treated or untreated, end sooner or later in a chronic inflammatory affection of the lymphatics of the central nervous system, giving rise to a characteristic train of symptoms progressive in their course and fatal in their issue, whilst on the other hand spirochæta infection produces disease of the nervous system in only about 5 to 10 per cent. of the cases of syphilis even untreated, and considerably less if treated. We may speak of two forms of nervous lesions: (1) the true syphilitic due to the action of the specific organism; and (2) the parasyphilitic due to a bio-chemical change in the body whereby the neurons die prematurely. Whereas it may be affirmed that in every case of sleeping sickness there is invasion of the subarachnoid space by the trypanosome, in only about 4 or 5 per cent. is there invasion of the subarachnoid space by the spirochætæ, and then in all probability they are confined within the lymphatics and do not become free in the cerebro-spinal fluid as do the trypanosomes. Whereas it appears that neither arsenic, antimony, nor mercury preparations will cure a patient who is suffering with sleeping sickness (that is, invasion of the cerebro-spinal fluid by the trypanosomes) in most instances arrest, and in some cases cure, is effected by the same drugs in syphilitic affection of the lymphatics of the central nervous system. Dr. Mott said that if the two organisms be observed by the ultramicroscope it would be noticed that the trypanosomes were extremely active, moving rapidly all over the field, whereas the spirochætæ progressed slowly in a screw-like fashion around their long axis. The former then would easily penetrate the delicate walled capillaries and escape into the cerebro-spinal fluid; moreover, observation showed that whereas trypanosomes could usually be easily found in the blood, spirochætæ cannot; they seemed to be only able to multiply in the lymph spaces and channels. So that the chances of affections of the nervous system in syphilis are infinitely small as compared with the chances in human trypanosomiasis. But in other forms of trypanosomiasis he was not aware that the cerebro-spinal fluid did become infected, and the deadly nature of infection by the gambiense might be due to the fact that it had acquired the habit of migration into the subarachnoid space. In both syphilis and human trypanosomiasis there was a polyadenitis; both diseases were characterised by a lymphocytosis in the blood, and when the nervous system was invaded by a lymphocytosis in the cerebro-spinal fluid. Dr. Mott said that organic arsenical, antimonial, and mercury preparations which had a trypanosomocidal and spirillocidal action might owe that property to either stimulating or phagocytic function, for those metals might have an affinity for the phosphorus containing lipoids of the osmotic membrane forming the periplasium of those organisms. Moreover, it was possible that the toxic effects of organic arsenical preparations so widely used for the cure of those diseases might be due to association of the poison with the lecithins of the nervous system. In trypanosomiasis it was extremely rare to hear of a recovery, but one had probably recovered that he knew of. The lesions of the central nervous system in sleeping sickness resembled in some ways both the lesions of syphilitic meningo-encephalitis and the meningo-encephalitis of general paralysis. But there were striking differences to both. Examination of the lymphatic glands in trypanosomiasis showed the presence of the organisms, and whether it was simply due to their mechanical presence or to a toxic secretion, a chronic inflammatory condition was set up in the glands and lymph channels of the body. The characteristic lesion in the brain and spinal cord was a diffuse infiltration of the perivascular and meningeal lymphatics of the brain with lymphocytes and plasma cells; this was occasioned by a proliferation of the endothelial cells and connective tissue elements of the lymphatic sheath of Robin and the pial sleeve; it is accompanied by a marked proliferation and hyperplasia of the neuroglia tissue which extended from the periphery of the central nervous system inwards. There was some degree of neuronic atrophy, but it was in no way proportional to the chronic inflammatory change. There were little or no naked-eye changes in the brain in uncomplicated cases. Dr. Mott contrasted that with syphilitic meningo-encephalitis where besides the meningo-encephalitis there were endarteritis and tendency to tumour formation. In general paralysis there was a perivascular infiltration of lymphocytes and plasma cells, resembling that of sleeping sickness, except that it favoured the cortex, whereas in sleeping sickness it was much more marked in subcortical structures. In general paralysis there was a neuroglia proliferation and hyperplasia proportional to the neuronic atrophy which was extreme and proportional to the degree of dementia. Rod cells, sprouting capillaries, and new vessels were seen in abundance.

CLINICAL SECTION.

Exhibition of Cases.—New Methods of Reading Arterial Blood Pressure.

A MEETING of this section was held on Oct. 14th, Mr. A. PEARCE GOULD, the President, being in the chair.

Mr. ALBERT CARLESS showed a case of Adiposis Dolorosa (?). The patient was a female, aged 31 years, who came under observation in March last for piles. She was admitted to hospital and operated on satisfactorily. She was always anæmic, with a poor circulation, her fingers and hands readily becoming blue in cold weather. From time to time she had noticed that the tissues beneath her chin became somewhat swollen, but that did not last. At the time of operation she had a small fatty growth in the back of the neck in the suboccipital region, but it caused her no pain or inconvenience. Between the months of April and June a marked fatty development occurred, affecting mainly the shoulders, the back of the neck, the root of the neck, the back, and the front of the abdomen. Those diffuse fatty masses had been decidedly painful and tender, and there had been some degree of neuralgic pain in the arms. The progress was very rapid up to June, but had been slower since. The most marked development had been around the shoulders and upper parts of the arms, and the disproportion between those regions and the parts below was very great. The periods had been regular and not specially painful, but the loss was not great; she missed one or two periods after the operation. The thyroid body appeared to be atrophied. The skin acted well, especially the arms and

hands. The patient generally felt languid and unfit for work. She had taken thyroid tabloids and pituitary extract. The former seemed to do her good and control the increase in size, but worried her eyes somewhat; the latter had no effect. She had increased recently in weight by five pounds.

Dr. H. D. ROLLESTON showed a case of Symmetrical Lipomatosis. The patient was a man, aged 45 years, without a history of syphilis. He was admitted for distension of the abdomen and some ascites, which had since passed off. There were almost symmetrical fatty masses over the clavicles, neck, the shoulders, arms, elbows, the lower abdomen, sacral region, and the upper and inner aspects of the thighs; some of them were large and diffuse, others small and circumscribed. The veins over the chest and the lipomas in the neighbourhood of the clavicles were dilated. The mammæ were considerably enlarged. Some of the large fatty masses appeared to be diffuse, others to be composed of separate tumours which were becoming confluent. Except in one or two spots there was no tenderness. The tumours were not spontaneously painful, and there had not been any local pain before the appearance of the tumours. The condition, therefore, was not adiposis dolorosa nor Dercum's syndrome. It approached but did not accurately correspond with Lyon's group of "diffuse symmetrical lipomatosis, with predilection for the neck." The fatty mass about the left clavicle was larger than its fellow, and was the first to appear. Knee-jerks, normal; sensation, normal; pulse, 70; temperature, 97° F.; blood pressure, 110 mm. Hg; urine, normal; weight on admission, 13 stones 7 pounds, now 11 stones 9½ pounds. Dr. G. Allpress Simmons reported that the screen examination showed a normal translucency of both lungs; the excursions of the diaphragm on both sides, even on deep inspiration, were not more than half an inch, and the arches did not flatten. A skiagram taken from the front showed some mottling of the inner half of the right lung towards the base. There was, perhaps, slight dilatation of the aorta, but no evidence of any intrathoracic tumour. A lateral skiagram of the neck did not show calcification. In regard to treatment the patient had recently been on small doses of thyroid extract (one and a half grains) and had had X rays to the right side of the body.

Dr. ALFRED M. GOSSAGE showed a case of Adiposis Dolorosa (?). The patient was a woman, aged 54 years, who had always suffered with pains in the legs. Catamenia became irregular at the age of 44 and ceased at the age of 48. From the age of 44 she had become very stout and the legs had become much more painful, so that it was difficult for her to walk. The patient was obese and had numerous fatty swellings on the legs and thigh, which were painful and tender. Over the rest of the body the adipose tissue was evenly distributed, but there was general tenderness. There was not any mental impairment.

Dr. H. G. TURNEY described a case of Physiological Obesity which developed into a case of Adiposis Dolorosa.

Mr. CARLESS, in commenting on the case exhibited by Dr. Rolleston, gave details of a case in which the venous enlargement was ascribed to pressure in the mediastinum.—The PRESIDENT remarked that in Dr. Rolleston's case the blood in the enlarged veins ran from the shoulder to the sternal region, which was against the condition being due to mediastinal pressure.—Dr. F. PARKES WEBER pointed out that typical cases of adiposis dolorosa occurred nearly always in women, whilst diffuse lipomata of the neck were found nearly always in males.—Dr. ROLLESTON referred to the fact that some cases of myxœdema developed an extraordinary degree of adiposity.—Dr. GOSSAGE said that the patient he showed had not improved under thyroid treatment.

Dr. GEORGE OLIVER demonstrated two New Methods (Auditory and Visual) of Reading Arterial Blood-pressure. The auditory method consisted of an air-tight tambour strapped over the brachial artery at the bend of the elbow below the armlet, the compression of which developed a loud throb or thud; and binaural auscultation of the pressure area of throbbing which afforded readings of the diastolic and systolic arterial pressures—half that area indicating the diastolic, and the cessation of the throb the systolic pressure. The readings thus obtained were more delicate, more definite, and more accurate than those afforded by extinction of the pulse (digital) and by the optimum oscillation. The visual method (the development of oscillation in a spirit index and its cessation) was also derived from the auditory tambour. It afforded a reading of the systolic arterial pressure (the armlet being applied to the arm or forearm) as sensitive as that furnished by the auditory method. It was suggested as a corroborative or alternative method, and might be useful when the hearing was impaired or when noises were distracting for auscultation.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Presidential Address.—Adenomatosis Vaginæ.—Vaginal Secretion in Infants.

A MEETING of this section was held on Oct. 6th, when the President, Dr. H. MACNAUGHTON JONES, delivered his Presidential Address.

Dr. VICTOR BONNEY and Mr. BRYDEN GLENDINING communicated a paper on Adenomatosis Vaginæ, a hitherto undescribed condition. A woman, aged 42 years, had suffered for 12 years from a persistent vaginal discharge of a transparent, sticky nature. The entire mucous surface of the vagina and portio vaginalis of the cervix was red and granular, being studded all over with small cysts, varying in size from that of a pin's head to that of a large pea. A continuous stream of mucous fluid like the white of an egg exuded from the diseased surface, in quantity about 6 ounces per diem, specific gravity 1014. Microscopical examination of the vaginal wall revealed numerous glandular spaces lined by a single layer of tall columnar epithelium, actively mucinogenetic, as proved by their reaction to mucicarmine. Here and there the communication of these glands with the surface of the mucosa could be demonstrated. After a careful consideration of several possible explanations of this rare condition Dr. Bonney and Mr. Glendining came to the conclusion that a congenital peculiarity of the cells lining the vagina existed, in virtue of which they possessed facultative gland-forming powers similar to those covering the vaginal cervix in immediate proximity to the external os uteri. This power had remained dormant until excited by inflammation or the effects of child-birth—a process analogous to that by which a glandular erosion of the cervix is formed. The paper was illustrated by drawings and micro-photographs shown on the epidiascope.

Dr. G. DRUMMOND ROBINSON read a short communication on Some Observations on Vaginal Secretion in Infants. The paper was based on the examination of the vaginal secretion of 50 infants varying in age from 30 minutes to 14 days. Within the first 48 hours the secretion was invariably found sterile, and sterile secretion was found as late as the thirteenth day. Dr. Robinson suggests that the organisms found in the vagina during the first fortnight after birth may really have been carried up from the vulva at the time when the cultures were made. Of the 44 cases in which the secretion was found sterile, in 36 (81·8 per cent.) the reaction was acid, in 5 (11·3 per cent.) it was alkaline, and in 3 (6 8 per cent.) it was neutral. The conclusions drawn from these observations are: (1) That the vaginal secretion is sterile for the first 48 hours after birth, and probably for a much longer period; and (2) that the vaginal secretion of infants is acid in the majority of cases, and that this acidity is not due to the action of micro-organisms.

The PRESIDENT then delivered an address on the Lessons of a Session, in which he pointed out the advantages to the section of the publication of a quinquennial digest of its proceedings, so as to rescue from oblivion in the catacombs of the Transactions of the Society the original work done during the previous years. He proposed to illustrate his meaning by giving such a brief digest of one session's work, in the original communications presented, the clinical histories detailed, and the pathological specimens exhibited. Dr. J. Curtis Webb's important review of the whole subject of Electro-therapy in Gynæcological Practice had shown that in ionisation we have an efficient therapeutic agent in cases specially selected for its employment. His paper, however, and the discussions which followed it, tended to prove that such electropathic treatment demands primarily three essential conditions—special training and skill in the applications of the kind of electricity used, its nature and quantity; accurate diagnosis and differentiation of the states in which it is contra-indicated; judgment as to its continuance or abandonment according to the effect it produces. Dr. Comyns Berkeley and Dr. Victor Bonney

drew, for the first time, a clear line of demarkation between the two affections Leucoplakic Vulvitis and Kraurosis Vulvæ. The relation that the pathological processes in each have to carcinoma vulvæ was compared, proving that coitus, sterility in younger women, advanced life, and in his (the President's) opinion prolonged vaginal discharge, are potent factors in causing the malignant change. Once its presence is suspected the landmarks for removal should lie completely outside the diseased area.

Justification for Cæsarean Section in Contracted Pelvis, in Placenta Prævia, and Eclampsia had been most thoroughly discussed through the communications of Dr. Hastings Tweedy, Dr. Henry Jellett, and Dr. F. J. McCann. In addition they had now before them the discussion opened by Dr. Amand Routh as "reporter" at the International Congress just held at St. Petersburg. These views raised the whole question of the indications for, and the relative advantages of, the classical and the extraperitoneal operations, as compared with symphysiotomy, pubiotomy, hysterotomy, and the usual obstetrical methods, such as the induction of labour, craniotomy or cephalotripsy, and high forceps. The Master of the Rotunda was strong in his denunciation of these latter steps in contracted pelvis, and he defined the degrees of deformity in which he considered the various operations were indicated. From the opinions expressed at the meeting of the American Medical Association in 1909, with those declared at the three meetings of this section this year, and at the recent Congress, we can summarise the present views of obstetricians on the indication for Cæsarean section in contracted pelvis, placenta prævia, and eclampsia. 1. Greater care generally should be taken in the early months of pregnancy to estimate approximately the pelvic capacity for labour at full term. 2. The time has come when the general indications for Cæsarean section, symphysiotomy, pubiotomy, hysterotomy, and the ordinary obstetric methods of dealing with contracted pelvis can be more exactly defined. 3. There is still a useful place for induction of labour, craniotomy, or cephalotripsy, and high forceps application. While ever regardful of the life of the child, that of the mother always takes precedence in determining our selection of the manner of delivery. 4. Cæsarean section has a place in the management of placenta prævia only when (*a*) this complication occurs under circumstances that would in any case demand the operation; (*b*) when the character of the presentation and nature of the placental attachment, with other conditions, render the classical methods of treatment impossible to carry out, or their practice more dangerous than operation. It would appear that the risk to the mother, which must be our first consideration, has been exaggerated by those who advocate the step. 5. Cæsarean section has a place in the treatment of eclampsia in exceptional cases, and these are included in the indications suggested by Dr. McCann—viz., the time of occurrence—before or during labour; the severity and rapidity of the fits; considerable disproportion between the head and pelvis; an undilatable cervix; and a moribund mother and a living child. 6. As to the advantages and disadvantages of the symphysic and the classical operations, Professor Bumm at the International Congress summed these up. In the former the avoidance of the peritoneum and easier suture of the cervix, but there is greater difficulty in technique, greater risk to the bladder, and the delivery of the fœtus more difficult.

In the discussion on Mrs. Scharlieb's statistics of Malignancy in Ovarian Tumours, it was shown that out of 3481 cases collected from various clinics 9·9 per cent. were malignant, and that in a fairly large proportion the degenerative change occurred primarily in the ovary. In ten instances remarkable Shrinking of Myomatous Tumours of the Uterus was shown to have occurred by Dr. Arthur Wallace. While this may occasionally happen, the statistics now published of some 8000 tumours prove that degenerative changes and danger to life from these growths increase directly in proportion to the advance in years after 40 to 50.

Dr. Macnaughton Jones concluded by referring to the interesting correlations between the pathological appearances seen in nuclei arising from the syncytium and the cells in chorioepithelioma which were demonstrated from a case of ruptured tubal pregnancy by Mr. T. Carwardine, to the possibility of treating rupture of the uterus successfully by vaginal suture as demonstrated by Mr. Herbert J. Paterson, and to the occurrence of pelvic hæmatocele, apart from ectopic gestation, as illustrated by Dr. Cuthbert Lockyer. Several clinical cases of great interest were referred to by the President; some bore on the question of operation on myoma complicating pregnancy or labour, as in Dr. Philip Turner's case of hysterectomy successfully performed 63 hours after labour for infection arising out of a necrobiotic fibroid, also Dr. H. Russell Andrews's successful myomectomy in the third month of pregnancy, complicated by a retroversion, hysterectomy for an incarcerated necrobiotic fibroid complicating pregnancy (Dr. T. W. Eden and Dr. T. G. Stevens), and the large myomatous tumour distending the vagina successfully removed during labour by Dr. Griffith. One of themost interesting cases brought forward he considered was that in which Dr. Herbert Spencer's posterior Cæsarean section was followed by hysterectomy for fibroids in the thirty-eighth week; the living fœtus and placenta having been extracted the degenerated and greatly thickened uterus was removed with safety to mother and child. He mentioned the following exceptionally interesting specimens: a complete transverse rupture of the fundus uteri (Dr. Lewers), carcinomatous degeneration in an adenofibromatous polypus (Mr. J. H. Targett), spheroidal-celled carcinoma of the cervix (Dr. Griffith), atresia in one-half of a double uterus (Dr. Lewers), abscess of the ovary due to infection from amœba coli (Mr. Barris and Dr. Williamson), ovarian pregnancy (Dr. E. Hastings Tweedy), implantation teratoma (Dr. V. Bonney), and several cases of ectopic gestation and molar pregnancy.

A vote of thanks to the President, proposed by Dr. G. E. HERMAN, and seconded by Mr. W. D. SPANTON, was carried by acclamation, and the meeting then adjourned.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Oct. 13th, Dr. M. Handfield-Jones, the President, being in the chair.—Dr. E. G. Graham Little showed two cases of Rodent Ulcer, one of which had been treated with ionisation and one with CO_2 snow. The first case, a man about 45, had had the ulcer six years. When first seen it was of about the size of a threepenny-piece, was typical in appearance, and was situated on the cheek near the nose. Two applications of zinc ions, of an average duration of 20 minutes each, had been made with an interval of a fortnight. The result had been very successful, only a faint atrophy being noticeable in the site of the former ulcer. Six months had elapsed since the last treatment, and there was no sign of recurrence. The man had felt very little pain during the applications, for which about 5 to 7 milliampères of current had been used. The second case was in a woman, aged 40; the ulcer was of about seven years' duration, typical in appearance, and seated at the outer margin of the right orbit. Three applications of CO_2 snow had been made, lasting 20 to 25 seconds each and separated by intervals of 10 or 14 days. The last treatment was six weeks ago and there was now no trace of disease, the site being a little red still, but otherwise apparently quite healed. Dr. Little also showed a case of Lupus Erythematosus of long duration; the patient, a man, aged 74 years, had been treated for the complaint 40 years ago by the late Erasmus Wilson. When first seen the face, ears, and backs of both hands were affected. CO_2 snow had been applied for 20 to 30 seconds at intervals of about a week. The result had been strikingly good: the hands had been practically cured as well as parts of the face; private affairs caused a temporary interruption in the treatment, but he had now returned for a further course and a treatment was given three days ago, and the blisters which resulted from the application were still partly unbroken. The method was exceedingly useful, and this case was a good illustration of the success which might be anticipated even in very chronic cases and in elderly persons.—Dr. A. M. Gossage showed a case of Splenomegalic Polycythæmia.—Mr. Peter L. Daniel showed two cases of Hirschsprung's Disease (Idiopathic Dilatation of Colon) Affecting the Rectum. The first case had been operated upon two and a half years ago; she was then 12 years old. She was born with an imperforate anus, and a history of severe constipation from the time this was perforated existed. The rectum and adjacent sigmoid were excised and an end-to-end anastomosis was carried out with excellent results. The second case, also a girl, aged 13 years, in a milder stage of the

affection, was reacting to injections of eserine (grain 1/100) three times a week so well that until this proved ineffective nothing further was intended. Skiagrams of the condition before and after operation were shown, also the excised rectum, which, with contents, weighed 6 pounds.—Mr. L. B. Rawling showed: 1. A case of Tumour of the Lower Jaw with Egg-shell Crackling; a skiagram showed the wisdom tooth (unerupted) situated at the top of the tumour. Mr. Rawling considered the diagnosis lay between a dentigerous cyst and a myeloid sarcoma; he proposed to operate. 2. A Cyst in the Shoulder presenting through the fibres of the deltoid beneath the scar of an old operation incision. It was at first considered that it might be a hernial protrusion of muscle, but an exploratory puncture produced fluid containing some melon-seed bodies. He considered it was a tuberculous affection and probably a protrusion of a pouch of synovial membrane from the joint itself; the nature of the previous operation was unknown. —Mr. J. E. R. McDonagh showed several cases in which marked and intractable syphilis had been treated with an injection of "606," all with surprising and almost immediate success.—Mr. Haldin Davies showed: (1) A case of Tuberculide; and (2) a case of Pigmented Nævus.—Mr. S. Maynard Smith showed a case of Cirsoid Aneurysm of the Scalp; this had been quite small at birth but after a blow on the head had considerably increased in size; he had treated it by multiple ligature, causing its almost complete disappearance.—Mr. E. Laming Evans showed a case of Congenital Upward Displacement of the Right Patella in a little girl.—The President showed some gynæcological specimens, and an interesting discussion followed.

OXFORD MEDICAL SOCIETY.—A meeting of this society was held on Oct. 14th at the Radcliffe Infirmary.—Dr. Tibbs related the history of a case of Lymphatic Leukæmia which had ended fatally in the infirmary. The course had been very acute; there had been high temperature, a septic throat, and the blood picture of the large-celled type. A blood culture was negative. The interest of the case lay in the fact that post mortem the glands and the pericardium were found to contain a Gram-negative diplococcus, which it had not been possible to grow in pure culture. Several preparations from the case were exhibited. The question was whether the case was one of chronic leukæmia with a terminal septic infection, as three weeks previously the patient had been in his usual health, and the patient volunteered the statement that his glands had always been enlarged.—Dr. W. Collier then read a paper on the Therapeutic Use of Alcohol. Pharmacologically it was an irritant, and its action in this respect on the stomach was stimulant. It was doubtful whether, on the nervous system, alcohol stimulated first and depressed afterwards or depressed from the beginning. The essays of Crile and Gairdner had had a very marked effect in altering Dr. Collier's treatment of his own patients and, he thought, that of many other physicians. Preceding the crisis in a fever Dr. Collier thought that ammonium carbonate, digitalis, and strychnine were as efficacious as alcohol. For fainting it was perhaps the most accessible drug, though it possessed no advantages over the preparations of ammonia. As a hypnotic it was doubtful if it was ever as useful as veronal and other similar drugs. As a means of warding off syncope in slight operations such as tapping it was a useful drug. For children with diarrhœa it was a useful adjunct to other methods of treatment, and to the aged it might be given with impunity. In facial neuralgia two glasses of port wine daily often had a marked effect, and during convalescence good wine in moderation more quickly restored the strength of the patient. The present fashion of giving meat-wine was wasteful and expensive treatment, and offered in persons not taking it under medical orders a likely means of developing a habit. The alcohol consumed in institutions had been markedly lessened in the last 15 to 20 years. In the Radcliffe Infirmary in 1889, when 1399 patients had been treated, £117 had been spent on malt liquors and £91 on wine and spirits; 20 years later, when 2257 patients were treated, £9 had been spent on malt liquors and £51 on wine and spirits. The records of other hospitals all showed enormous reductions in the consumption of alcohol.—In the discussion which followed Mr. R. H. A. Whitelocke urged its vigorous use in all cases of septic poisoning.—Dr. F. G. Proudfoot doubted whether in slight operations ammonia preparations had the same effect as alcohol. He mentioned its diuretic action and the varying action of different preparations of alcohol, such as beer and whisky, in this respect. In digestion its action depended entirely on the individual.—Dr. W. J. Turrell urged its value for tiding over a period of great fatigue in long-continued muscular exercise; for instance, towards the end of a long bicycle ride. It was a valuable drug in children and old people. According to Graves, it was valuable if the pulse and respiration remained steady. He also thought that it was a valuable hypnotic and as a stimulant to the appetite in fatigue.—Mr. A. P. Dodds-Parker related that in the records of two physicians at a certain London hospital the percentage mortality in the patients of the one who gave alcohol freely was half that of another physician who withheld it. In septic cases he thought that it was of little use, and much preferred in his own practice to give lactose as a means of keeping the tissues of the body supplied with a minimum of food.—Dr. W. Duigan said that in his experience alcohol in asthenic conditions, as, for instance, bad influenza, was a valuable drug, and in continued fever of an asthenic type.—Dr. W. A. P. Waters mentioned its value in his hands after acute illnesses, especially in children.

Reviews and Notices of Books.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. No. 37, Investigations on Bengal Dietaries, with Some Observations on the Influence of Dietary on the Physical Development and Well-being of the People of Bengal. By Captain D. McCAY, M.B R.U.I., I.M.S., Professor of Physiology, Calcutta Medical College. Calcutta: Superintendent of Government Printing. 1910. Price Rs.2.6, or 4*s.* 3*d.*

THIS volume contains an account of a prolonged and exhaustive investigation into the composition and food value of the dietaries that are in use in the various jails in Bengal, with some valuable observations on the physiology of alimentation, and practical recommendations for improvement in existing conditions. The scope of the inquiry was to investigate the suitability of the diet scales prescribed for prisoners in Bengal. Most of the work done has related to the estimation of the nutritive value of the dietaries in use, and in particular to the determination of the digestibility, or absorbability, of the nutritive principles contained in them. It has been laid down by recent authorities on the physiology of nutrition (e.g., Atwater) that in foods most easy of digestion and absorption, such as meat, fish, and eggs, the protein is utilised to the extent of 97 per cent.; while with other articles, equally nutritious and necessary for the animal economy, such as bread, cereal grains generally, and fruit, its digestibility coefficient is 83 to 85 per cent., and with the leguminosæ about 76 per cent. The most important result of Captain McCay's investigation has been to prove that, as regards the protein of the dietary, the degree of its absorbability depends very largely on the actual quantity or bulk of the food consumed. This question of bulkiness is not of much moment in European and American dietaries, but in many parts of India and the East, and particularly in Bengal, it is of the first importance; the average weight of cooked food consumed in a day by a Bengali prisoner amounts to about 140 ounces, or more than 8½ pounds. (It should be remembered that the Bengali in jail is better fed than his friends and relations outside, but the character of the dietary is the same.) It was found that with this diet protein absorption was barely 55 per cent., instead of the theoretical 76 to 85 per cent. Another factor tends to reduce the net alimentary value of the Bengali's dietary. The energy value of a dietary is the total potential energy of the food minus that of the corresponding fæces and urine. With the dietaries universally in use in Bengal excessive fermentative changes take place in the carbohydrate

constituents while passing down the alimentary tract; sugar and starch are converted into carbon dioxide and fermentation products (acetic and lactic acids, &c.) of low caloric value, and a great deal of potential energy is lost. Moreover, intestinal troubles are extremely prevalent, leading to malnutrition.

After an introduction giving a *résume* of work that had been previously done in regard to Indian jail dietaries, and of the methods employed in the present investigation, the author describes the dietaries at present in force and gives their chemical composition; also their energy value as determined by means of the calorimetric bomb by Professor Benedict of Washington, an act of international scientific courtesy that is gratefully acknowledged. Then follows a detailed account of the experiments on the nutritive value of the dietaries, first in Lower Bengal jails, then in those of Behar. The Lower Bengal dietary consists of 26 ounces rice, 6 ounces *dal* (pulse), 6 ounces green vegetables, and condiments; it contains 93 grammes protein, 693 grammes carbohydrates, and 30·5 grammes fat, yielding 3508 Calories, a higher value "than any of the standard diets that have been formulated for Europeans," but the author shows that, by reason of the excess in carbohydrate (leading to excessive fermentation), the absorption of the protein is so much interfered with that its value is reduced to 60 or 65 grammes. This was proved by very numerous experiments. Batches of five or ten or more men were carefully observed, their urine analysed in five-day periods, and the metabolism calculated. In some series of observations not more than 50 per cent. of the nitrogen ingested was metabolised. The carbohydrates were gradually reduced in amount and a succession of observations made on the nitrogen excretion under the altered conditions. It was found that when the rice ration was 18 ounces (instead of 26 ounces) the nitrogen absorbed amounted to 8·5 grammes (instead of 7·5). "Any rice in the dietaries in excess of 18 ounces per man daily is not only useless but actually clogs the absorption of protein, so that the amount of nitrogen undergoing metabolism actually falls."

In the jails in Behar (which is Upper Bengal) the quantity of rice allowed is only 16 ounces, the same amount of pulse (*dal*) is given as in Bengal—viz., 6 ounces, and either 10 or 12 ounces of *ata*, a flour prepared either from wheat or maize, which contains protein. The value of this diet is approximately 105 grammes protein, 650 grammes carbohydrate, and 38 grammes fat. The diet is less bulky than the Bengal diet, but there is too much carbohydrate to permit of the best use being made of the protein element. The recommendations made are: for Bengal jails a diet of rice (Burma or country) 18 ounces, pulse 4 ounces, wheat ata 4 ounces (or fish 4 ounces in its stead twice a week), and vegetables 6 ounces; for Behar jails: rice 12 ounces, *ata* either 10 ounces (from wheat) or 12 ounces (from maize), pulse 5 ounces, vegetables 6 ounces, and on two days a week 5 ounces of fish or goat's flesh in place of 2 ounces *ata* and 1 ounce *dal*. The general effect would be to decrease the quantity of rice all over Bengal by 6 ounces daily, which would work out to a saving of 75,000 rupees (£5000) per annum. It seems strange to read (p. 44) that "it was found practically impossible to get the prisoners (in the Presidency jail, Calcutta) to consume the full diet (26 ounces) of Burma rice for more than a day or two;" the same was found at Buxar jail (p. 102). There must have been a great accumulation of surplus stores in these institutions. Country rice, on the other hand, is consumed in its full quantity.

The general result of the inquiry is to demonstrate that while in chemical value the Bengal diet contains 93 and the Behar diet 106 grammes protein, the nutritive or physiological values are only 49 and 60 grammes respectively—that is, a little over 50 per cent. only of the protein is absorbed, the cause of this low absorption being the excessive bulkiness of the food. By a succession of careful trials it was found that the optimum quantity of rice was 18 (instead of 26) ounces in Bengal and 12 (instead of 16) ounces in Behar.

In the second part of the volume is a very suggestive discussion of Chittenden's views as to the possibility of existing in health on a diet containing less than half the protein content of diets ordinarily in use in Europe and America. In his previous memoir Captain McCay had shown that this is the case in Bengal, the average native reaching an even lower limit of nitrogenous metabolism than any of Chittenden's subjects; many students and fairly well-to-do persons exist on a metabolism of less than 40 grammes of protein daily. But when it came to judging of the effects of such a dietary on physical development, capacity for labour, and resisting power to disease and infection, it was found that Chittenden's standards were not sufficient. The Bengali diet is contrasted with that of the Behari; the latter (in the jails and in the population generally) is about 2 grammes per head higher in nitrogenous metabolism than the former. "In accordance with this we find in the Behari a much better physical development, greater capabilities for muscular exertion, a distinctly greater degree of vivacity, briskness, and sprightliness of manner." His weight is 120 pounds, compared with the 110 pounds average of the Bengali. This results from the 10 per cent. higher nitrogenous metabolism. It is also pointed out that the low nitrogenous metabolism of the Bengali does not secure him from renal disease, the particular condition that Chittenden considers to be most likely to be avoided by protein economy, for renal disease is much more common among the working population of Bengal than in Europeans. A comparison is also made between the hill tribes to the same effect, and the conclusion is come to that "in those races where an assimilable protein, and particularly an animal protein, forms part of the ordinary diet, muscular development and good fighting qualities seem to be intimately related with the level of nitrogenous metabolism attained."

The present memoir by the professor of physiology at Calcutta is of permanent scientific value, and second to none of its predecessors in interest or importance.

Handbuch der Kinderheilkunde. Edited by Professor Dr. M. PFAUNDLER and Professor Dr. A. SCHLOSSMANN. Second edition. Four volumes, with 69 coloured plates and 515 illustrations. (Fifth volume in preparation.) Leipsic: F. C. W. Vogel. 1910. Vols. I. and II. Price each volume, unbound, M.12.50; bound, M.15. Vol. I., pp. 455; Vol. II., pp. 588.

IT is difficult within the limits of a review to do justice to the many additions and improvements which have been introduced in this new edition of a famous text-book. Much has occurred in the domain of pædiatrics since the first edition appeared in 1906, and it is scarce exaggeration to state that no event of importance remains unchronicled in these pages. That this vast and comparatively expensive handbook should have been translated into two languages—English (reviewed in THE LANCET of Feb. 6th, 1909) and Spanish—and yet require a new edition within four years of its first appearance, adequately testifies to the intrinsic merits of the work and to the position which pædiatrics now holds in the world of medicine. In its completed form this new edition will be enlarged by an additional volume and thus consist of five volumes and not four, as in the original issue. The new volume will be concerned with the surgical and orthopædic aspects of the diseases of children and will be the joint work of Professor

F. Lange of Munich and Dr. H. Spitzy of Gratz. The present review is, however, limited to a consideration of Volumes I. and II. only.

The first volume deals with such general subjects as nutrition and metabolism, diseases peculiar to definite age-periods, and with the general pathogenesis, pathology, treatment, and prevention of diseases in children. In only two of the chapters which deal with these subjects is there any noteworthy change—namely, in the one concerned with mortality and morbidity in childhood, written by Professor Prausnitz of Gratz, and in the one on nutrition after the first year, written by Professor Schlossmann himself in conjunction with Dr. P. Sommerfeld of Berlin. The first of these chapters is enlarged and brought up to date, but even in its present form it hardly does justice to the importance of the subject. The second has been entirely rearranged with the change in authorship. This chapter, though an important one, is not likely to appeal to English readers. In the first and theoretical section the feeding of children is expressed in calorie values, a method which, despite its scientific and abstract interests, has few practical applications in the feeding of the human animal, which has tastes, fancies, and idiosyncrasies of digestion and metabolism, all having a way of upsetting the most carefully laid plans. The second section of this chapter, which is concerned only with practical dietetics, also has its limitations, for German foods and methods and times of feeding hardly harmonise with English ideas.

The second volume shows many more important changes. Moreover, it comprises subjects which are of greater clinical interest and importance. The contents of this volume are: Blood diseases, by Dr. A. Japha of Berlin; constitutional diseases, by various authors; acute infections and chronic infections, both written by a variety of distinguished members of the profession. Barlow's disease, or infantile scurvy, if we mistake not, was included in the first edition in the chapter which was devoted to rickets; in this edition it has conferred on it the dignity of a chapter to itself from the pen of Dr. W. Stoeltzner of Halle. The chapter on rickets has itself been greatly enlarged by Professor W. v. Starck of Kiel, and now provides the reader with a more comprehensive account of the etiology and pathogenesis of the disease. The latter elaborates the theory at which he only hinted in the first edition, that the disease is primarily an osseous and muscular dystrophy, and dependent on the factors of domestication and confinement. In this connexion he makes honourable mention of Findlay's experimental work on puppies. Young animals kept in confinement, and especially under conditions of overfeeding, do not give full play to their natural instincts for muscular exercise. The inaction of the muscles deprives the growing bones of their healthy and natural stimulation. Professor Starck draws attention to the influence of internal secretions such as those by the adrenal organs, and refers to the antagonistic action between their secretion and that of the pancreas.

In a new and very excellent chapter Professor Pfaundler discusses the part played by diathesis in disease, and he reviews the claims of such conditions as neuro-arthritism, lymphatic disease, and the exudative diathesis to be regarded as independent entities, or as merely accidental syndromes of symptoms. He gives full prominence to Czerny's views on the exudative diathesis and his treatment by a restricted diet and unstimulating psychological environment. He also refers at length to the views of Buchard and his school with reference to the part played by a sluggish metabolism in the determination of such dyscrasias as gout, arthritis, and fatty disease (Fettsucht). The prominence given to the views of this French school is in marked contrast to the manner in which they have been heretofore ignored in Germany.

Duke's "fourth disease," which, it will be remembered, was described in a separate chapter in the first edition, receives fuller notice in the present volume, and additional evidence is adduced in support of its claims to be regarded as an independent infectious exanthem. Following on this chapter is another from the pen of Professor Pfaundler on "erythema infectiosum," an infectious exanthem 300 cases of which have been recorded in German literature. This disease has been described under various synonyms; for instance, Plachte originally called it megalerythema epidemicum, while Pospischill gave it the name of erythema simplex variabile; by others it has been called erythema simplex marginatum, erythema infantum febrile, and "the fifth disease." Professor Pfaundler declares for its independent existence as a disease *sui generis*. He describes the symptoms and course of the disease with detailed accuracy. The importance of being able to diagnose this exanthem from scarlet fever, or indeed from measles, lies in the fact that its comparatively harmless character does not necessitate prolonged isolation. The troubles of the practitioner in making a differential diagnosis between scarlet fever, German measles, the fourth and the fifth disease, would be greatly mitigated if it could be shown that they are due to infection by polymorphic varieties of one and the same microbic agent presenting different degrees, or indeed kinds, of virulence. The fact that these diseases are not mutually protective does not entirely dispose of this possibility.

The joint editors of these volumes are to be congratulated on the completion of a task of great magnitude. Not one of the least of their difficulties must have been to eliminate a conflict of opinion between the numerous and distinguished contributors who have taken part in this literary symposium. We notice in these two volumes greater uniformity and less reiteration than in the former edition; such a result implies most careful and painstaking editorship and a broad-minded appreciation of the criticism of reviewers.

Medical Electricity and Roentgen Rays. By SINCLAIR TOUSEY, A.M., M.D., Consulting Surgeon to St. Bartholomew's Clinic, New York City. With 750 illustrations, 16 in colour. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 1116. Price 30*s.* net.

THIS is a voluminous work which will form a valuable, if ponderous, addition to the library of the specialist in medical electricity and radiology. The subjects are from the beginning treated in the most exhaustive manner, and every point is illustrated with suitable diagrams and drawings. The first section deals with the physical problems involved, and runs to nearly 300 pages. Considering that this is a medical work we think that this part might have been very considerably curtailed. The section on electrophysiology is distinctly good and complete. This first portion of the book, consisting of 340 pages, might well form a volume by itself for the more convenient use of those who seek a useful laboratory handbook. In the chapter on electro-pathology the author describes the effects of lightning and high- and low-tension currents on the tissues and organisms as a whole—a subject that becomes of daily increasing importance with the rapidly extending use of electricity for industrial purposes. We note that he makes no reference to the work of Jellinek of Vienna, whose contributions to the study of electric shock are of the first importance. Subsequent sections deal with the subjects of electro-diagnosis, ionic medication, one on general electrotherapeutics being strikingly brief. After a short reference to the effects of the electro-magnet the author passes on to the use of electricity in nervous diseases, but leaves us with the impression of a lack of completeness, and not greatly convinced of the efficacy of the methods advised.

High-frequency currents are treated at some length and

appear to find favour with the author for many conditions. He considers such applications of decided value in cases of pulmonary tuberculosis. On p. 558 is a radiograph of a patient's chest who had been treated by this method among others. He states that after three months the patient had very greatly improved; he has omitted, however, to give a radiograph of the chest before treatment, which would have been valuable for comparison. The patient died about a year later, but the author thinks the case might have been cured had the patient been able to follow up the treatment, a sanguine view which he does not support adequately. When he comes to the treatment of local conditions and skin lesions by high-frequency currents, the author is on surer ground, and records and illustrates some definitely valuable results, though we do not quite see the reason for illustrating a typical case of alopecia areata that is under treatment at the time of writing, and apparently unchanged. He has had excellent results in pruritus, psoriasis, and chronic ulcers.

A short chapter is given on phototherapy, and then follows the section on the X rays which takes up the rest of the volume except for a few pages at the end which are devoted to the consideration of radium. This X ray section has been very carefully prepared, and we notice a novelty in the form of a cellular diaphragm with which the author claims he can get better definition in his radiographs. It has the effect of intercepting the stray rays to an even greater extent than the ordinary tubular diaphragm. The methods advised in radiography call for no special mention, except that the technique employed in any part of the body is fully explained and illustrated. A short chapter is devoted to X ray treatment, which also calls for no special mention. We note that the author does not claim any higher value for the X ray treatment of malignant disease than it deserves.

The book as a whole is a very valuable contribution to the literature of the subjects treated, but we think it might have been condensed in many places with advantage. The work could have been made less unwieldy by issue in two separate volumes. The printing and illustrations are of a high order and leave nothing to be desired.

Uric Acid in the Clinic. A Clinical Appendix to "Uric Acid as a Factor in the Causation of Disease." By ALEXANDER HAIG, M.A., M.D. Oxon., F.R.C.P. Lond., Senior Physician to the Metropolitan Hospital and the Royal Hospital for Children and Women; late Casualty Physician to St. Bartholomew's Hospital; assisted by KENNETH G. HAIG, L.R.C.P. Lond., M.R.C.S. Eng. London: J. and A. Churchill. 1910. Pp. 306. Price 5*s.* net.

IN this book Dr. Haig gives descriptions of cases illustrating his views regarding the pathogenic effects of uric acid. It is to be regarded as a clinical appendix to the well-known book in which he has enunciated his opinions; at the same time he has further developed them in the commentaries he gives upon the cases described. He maintains that the diseases or conditions caused by uric acid fall into two groups, the first being the collæmic group, in which he believes that the blood is thickened and its circulation hindered by floating particles of colloid uric acid; and the second the precipitation or retention group in which local retention of uric acid leads to irritation or pain. The collæmic group is subdivided into conditions due to simple collæmia, such as headache, epilepsy, neurasthenia, mental depression, asthma, insomnia, and various other conditions and groups of symptoms. The second subdivision is described as collæmia complicated by an organic factor, and comprises dyspepsia, chorea, Bright's disease, glycosuria, diabetes, high blood pressure, Graves's disease, Raynaud's disease, &c. In the retention group the ordinary gouty conditions are included, as well as arthritis, endocarditis, catarrhs, and cutaneous manifestations. Dr. Haig insists that these various conditions are not sharply marked off from one another and that they are not diseases, but are in all varieties and combinations the results of food poisoning. He discusses the effects of what he describes as a "uric-acid free" diet on these conditions. He divides drugs into solvents and precipitants, and climates are similarly classified. The data given in this book are for the most part simply illustrative cases, and for critical purposes must be considered in connexion with the original work.

LIBRARY TABLE.

The Expectation of Life of the Consumptive after Sanatorium Treatment. By NOEL DEAN BARDSWELL, M.D. Edin., M.R.C.P. Lond., F.R.S. Edin., Medical Superintendent, King Edward VII. Sanatorium. London, Edinburgh, and Glasgow: Henry Frowde and Hodder and Stoughton. 1910. Pp. 130. Price 3*s.* 6*d.* net.—Few tasks are more difficult than that of appraising the value of any method of treatment in a chronic disease of variable type such as pulmonary tuberculosis. A careful study of the after-histories of cases treated at sanatoriums is calculated to afford useful information in regard to the results of that method of treatment. Dr. Bardswell gives a careful statistical study of 241 patients who were under his care in sanatoriums during the years 1899 to 1905. He classifies his cases according to their condition on admission into three groups—viz., incipient, moderately advanced, and far advanced. He gives the results at the time the patients left the sanatoriums and also in 1909. Of the 241 patients, as many as 101, or 45 per cent., were dead in 1909, while 99, or 41 per cent., were classified as "well," and 15, or 6·2 per cent., as "alive"—i.e., "the patient has to make the care of his health his chief consideration in life, possibly to the exclusion of everything else." When the cases are studied in their respective classes the results are less gloomy, for of the 62 incipient cases, 46, or 74 per cent., were classified as well; 1, or 1·6 per cent., as alive; and 11, or 17 6 per cent., as dead, 4 being lost sight of. Among the moderately advanced cases 36·8 per cent. had died, and among the advanced cases 88 per cent. Dr. Bardswell examines his statistics by various methods and gives an interesting commentary upon the results obtained. His conclusions are temperate and practical and he makes no exaggerated claims as to the value of sanatorium methods. His little book is a useful contribution to a subject which is now widely discussed.

Nursing in Diseases of the Eye, Ear, Nose, and Throat. By the Committee on Nurses of the Manhattan Eye, Ear, and Throat Hospital. London and Philadelphia: W. B. Saunders Company. 1910. Pp. 281. Price 6*s.* 6*d.* net.—This is a good little book upon the nursing of sufferers from eye, ear, nose, and throat diseases. In detailing the general duties of sick-nursing, as well as those called for in special diseases, its range is large, nevertheless it avoids superficiality or tiresome minuteness, and is full of invaluable hints clearly and plainly set down. In the treatment of emergencies there is little or nothing omitted that is likely to prove of use to the attendant, and we would refer to the instructions given for the stilling of epistaxis as particularly serviceable. In the after-treatment of tracheotomy the steam tent is recommended as if it were indispensable. Doubtless climatic conditions render it advisable in many quarters of the globe, but we believe that in London experience has shown that tracheotomy cases do perfectly well, as a rule, when exposed to the ordinary ward atmosphere. We should have been glad of fuller details on the important matter of the procedure and after-treatment of the major operations on the nose and ear. As a rule, purely medical points are wisely omitted, but one among those included—namely, the statement that nasal septal

resection should not be undertaken under the age of 14 years—is inaccurate. Apart from these slight criticisms, we confidently recommend the book as a handy guide in the nursing of the special diseases in question, and much of its contents is worthy of the attention not only of nurses but also of surgeons.

The Law Relating to Pauper Lunatics. By SYDNEY DAVEY, B.A., LL.B., of the Middle Temple, Barrister at Law. Second edition. London: The Poor-law Publications Company. 1910. Pp. 283. Price 6*s.* net.—A law-book naturally has to be kept abreast of legislative change and of the development of the law by judicial decisions, so that a second edition of a convenient manual dealing with the law upon a particular subject may be called for after seven years, even though no new statutes of any importance affect its subject-matter. At all events Mr. Davey has no great legal novelty to record, and the recently decided cases which he now incorporates deal with such questions as the reimbursement of the expenses of maintenance and with other topics of interest to guardians responsible as such for the finances of their union rather than to the officers to whom is entrusted the medical care of the pauper lunatic. Medical officers of unions will, however, find their duties and obligations succinctly stated by the author under appropriate headings, the Lunacy Act of 1890 being the principal source from which these are derived. An appendix to the text contains all necessary forms, and the table of contents and index are such as to render readily obtainable any information that is included and that may be sought for.

The Death-Dealing Insects and Their Story. By C. CONYERS MORRELL. Manchester: H. A. W. Offices. 1910. Illustrated. Pp. 79. Price 1*s.*—This little work, written by a medical man who has travelled much in tropical countries, is intended mainly for the purpose of instructing and educating the laity, particularly those who are about to take up residence in a warm climate. Its object is to explain as clearly and as forcibly as possible, in language free from medical and scientific technicalities, the mode in which certain common but serious tropical diseases are conveyed to man through the instrumentality of insects, and the means by which such transmission may be prevented. A considerable portion of the book is naturally devoted to mosquitoes, the transmitters of malaria, yellow fever, and filariasis, and a full description is given of the malarial cycle. A chapter is devoted to sleeping sickness and the tsetse flies, and another to plague and the rat flea. Finally, a chapter is added on ticks and disease, though, as the author says, the tick is not, strictly speaking, an insect. We strongly recommend the work to those about to reside in the tropics. The author's style is clear and interesting, and his statements are easy of comprehension by non-medical readers. We may, however, be permitted to point out that the description of the measures in connexion with the prevention of plague needs some modification. For example, on p. 72 it is stated that "in cases where a ship is infected she is placed in quarantine and no one is allowed to land until the authorities are satisfied that the vessel is free from infection." In most civilised countries quarantine is now abolished and a more sensible and humane policy is carried out, under which immediately upon the ship's arrival the plague patient is landed for isolation and treatment on shore, the vessel being only detained until disinfection can be carried out, while passengers, under certain safeguards, are free to proceed without delay to their destinations.

JOURNALS.

Paludism: Being the Transactions of the Committee for the Study of Malaria in India. Edited by Major S. P. JAMES, I.M.S. Simla: Government Central Branch Press. 1910.—This new journal is one of the outcomes of the conference convened by the Government of India and held at Simla in October, 1909. At that meeting it was decided to establish an organisation which should deal specially with the difficult problem of malaria in India, including investigation of the epidemiology and endemiology of the disease. In connexion with this organisation a central scientific committee was appointed comprising the following officers—viz.: Lieutenant-Colonel J. T. W. Leslie, C.I.E., I.M.S., the Sanitary Commissioner; Lieutenant-Colonel D. Semple, R.A.M.C., director of the Central Research Institute, Kasauli; Major S. P. James, statistical officer to the Government of India in the Medical and Sanitary Departments; and Captain S. R. Christophers, I.M.S., assistant to the director of the Central Research Institute. It was also resolved to establish a Central Malaria Bureau at Kasauli, and to issue a journal under the title of "Paludism," of which Major James was to act as editor. The first number of this journal is now before us, comprising over 50 pages of printed matter. In an "editorial record" Major James sets out the main circumstances leading up to the appearance of the new periodical, the future numbers of which, it is expected, will be issued every three or four months. Following this editorial is an article on Investigations Relating to Quinine, in which a number of questions are formulated for the guidance of inquirers. These questions are subdivided into those relating to the treatment of primary cases of malaria, the after-treatment (treatment to prevent relapses), the treatment of apparently healthy malaria carriers, and the prevention of new infections. A memorandum is submitted containing questions to which the central committee desire answers respecting endemic and epidemic malaria. Another contribution is a short syllabus of the work done at the malaria classes for medical officers held at Amritsar during March and April of the present year. Captain Christophers contributes a valuable article entitled "Suggestions on the Use of Available Statistics for Studying Malaria in India." These suggestions cannot fail to be of great service to workers on the subject. The editor gives some "Notes on Mosquitoes," including a description, with illustrations, of a new anopheline, *Christophersia halli*; he also furnishes some observations on the generic position of the anophelines *stephensi*, *willmori*, and *rossi*, and also on the prothoracic lobes or patagia of anophelines. The number concludes with a digest of recent literature on malaria in India and in other countries. This new periodical should have success, for there can be little doubt of its proving of great use not only to the workers in India for whom it is primarily intended, but also to investigators in other parts of the world where malaria prevails. It seems to be the intention of the central scientific committee to make the Central Malaria Bureau at Kasauli and its quarterly journal *Paludism* achieve for malaria in India what the Sleeping Sickness Bureau in London and its monthly bulletin have done in advancing the study of trypanosomiasis.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on Oct. 13th, Mr. BUTLIN, the President, being in the chair.

The SECRETARY reported the death, on Sept. 11th, of Mr. John Langton, past Vice-President, and past member of the Council and of the Court of Examiners. It was resolved—

That the Council hereby express their deep regret at the death of Mr. John Langton, past Vice-President of the College, and their sincere sympathy with his widow and family in the loss which they have sustained.

That the Council do also record their appreciation of the services rendered to the College by Mr. Langton as a Vice-President and member of the Council and of the Court of Examiners, and their respect for

the devotion which he displayed in the work which those offices imposed upon him.

The best thanks of the Council were given to the President for the gift of his collection of sketches of early cancer of the tongue and conditions which may be mistaken for early cancer. The best thanks of the Council were given to Professor F. W. Bird of Melbourne for the gift of his collection of stereoscopic radiographs of anatomical and pathological subjects, and also to Dr. C. G. Seligmann for presenting a number of New Guinea skulls.

Mr. RICKMAN J. GODLEE, on behalf of the Committee on the Annual Report of the Council, submitted a draft copy of the report to be presented to the Fellows and Members at the annual meeting on Thursday, Nov. 17th. The report was approved and adopted.

Mr. J. F. Colyer was elected a member of the Board of Examiners in Dental Surgery, and Mr. Godlee was reappointed a member of the Committee of Management.

It was resolved to recognise the Great Northern Central Hospital as a place of instruction for the Final Fellowship.

Mr. Gerald Gibbon, till lately a student of Epsom College and now of St. Bartholomew's Hospital, was nominated the Eighteenth Jenks Scholar.

A vote of thanks was given to Dr. Amand Routh for representing the College at the recent International Congress on Gynæcology at St. Petersburg.

THE NEW CALENDAR.

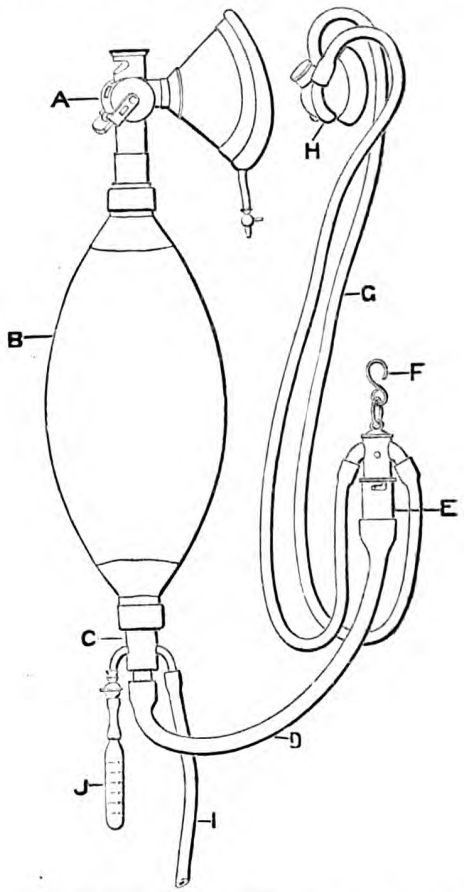
The Calendar of the Royal College of Surgeons of England for 1910–11 has been published by the Council of the College. There is now included in the Calendar a list of the trustees of the odontological collection which is housed at the College, whilst lists of the Masters of the Company of Surgeons, of the members of the Court of Assistants, and of the Court of Examiners from 1745 to 1800 have also been added. Considerable alteration in the text of the regulations for the examinations for the various College diplomas has been necessitated by the admission of women to the examinations. The Fellows of the College now number 1487, an increase of 30 over that of last year. There are 1449 Fellows admitted by examination, 29 elected as Members of 20 years' standing, eight "Fellows by election," and only one Fellow now remains "elected ad eundem." The number of Members on the roll is 17,030, an increase of 73, whilst there are 2263 Licentiates in Dental Surgery and 674 Diplomates in Public Health. The number of Licentiates in Midwifery is getting smaller each year and only 323 now remain. Mr. G. Carrick Steet, aged 92 years, the oldest Fellow of the College, is, and has been for a considerable time, a resident of London. The oldest Member, Mr. Edgar Jones, who is in his 101st year, resides in Essex.

The Secretary's report of the proceedings of the College Council during the past year occupies many pages of the Calendar and contains much interesting matter concerning the proposed combination with the University of London, the jubilee of the College Licence in Dental Surgery, and the administration of anæsthetics. With regard to the Museum, the superintendence of which is entrusted by the Council to a committee of its members, a summary of the progress made in the preservation, arrangement, and augmentation of the collection is contained in the Calendar. The institution of a historical collection has been carried out, and it contains preparations from the general collection which illustrate the diseases of eminent and famous personages or illustrate past medical and surgical methods and beliefs. The new card catalogue has now been instituted and four cabinets have been specially constructed for the same and placed in the entrance hall of the Museum. The large and important pathological department and also the gynæcological section are now being re-catalogued, and the new illustrated guide to the Museum has already been sold to a large number of visitors. The library of the College has had many valuable donations made to it, including 18 works published by the professors and distinguished alumni of the University of Geneva on the occasion of its 350th anniversary; a reproduction of the "Tabulæ Anatomicæ Sex" of Vesalius, privately printed for Sir William Stirling Maxwell in 1874 and now presented by his son, Sir John Stirling Maxwell; and the manuscripts of the late Sir James Paget from his son, Mr. Stephen Paget. Sir John Tweedy has also made many valuable presentations to the library numbering some 21 volumes, and has also been the means of acquiring for the College three very rare early printed books. The number of readers who used the library during the year was 10,413, a considerable increase on the number for the previous year. Particulars of the various prizes offered for competition by the College are given in the Calendar in full, together with a list of the several recipients since they were instituted.

New Inventions.

A COMBINED ORAL AND NASAL NITROUS-OXIDE INHALER.

I HAVE designed this inhaler and find it of great use in nervous patients and in those with nasal obstruction who cannot breathe through the ordinary nasal inhalers; also in hairy subjects, those with short upper lips, and the edentulous,



A, 3-way stop-cock and face-piece. B, Gas-bag for N_2O. C, Valved outlet tube supplying gas to nose-piece tubes. D, Flexible tube connecting portions C and E. E, Metal terminal with side outlets connecting with nasal supply tubes. F, Hook for suspending inhaler at side of chair. G, Supply tubes to nose-piece. H, Metal nose-piece with expiratory valve. I, Supply tube from cylinders. J, Graduated glass tube for use with ethyl chloride.

on whom it is difficult to fit other nasal apparatus accurately. It is quite simple to use and gives excellent results where prolonged gas anæsthesia is required. It can be used for ether and ethyl chloride with or without gas. It has been manufactured for me by Messrs. C. Barth and Co.

T. GRAHAM SCOTT, M.R.C.S. Eng., L.R.C.P. Lond.,
Senior Anæsthetist, Great Ormond-street Children's Hospital; Senior House Anæsthetist, Royal Dental Hospital, London.

THE LANCET.

LONDON: SATURDAY, OCTOBER 22, 1910.

The Catholic Spirit in Scientific Inquiry.

IT is a striking tribute to the profound genius of WILLIAM HARVEY that in the long series of distinguished physicians who have been called on to deliver the oration commemorative of his fame, so many should have dwelt on the remarkable manner in which the most recent pre-occupations of modern biology are often foreshadowed in the writings of the great English physiologist of the seventeenth century. The Harveian orator for this year, Dr. H. B. DONKIN, whose address, delivered before the Royal College of Physicians of London on Oct. 18th, is published in full in our present issue, has followed this precedent, while selecting as the material of his excellent oration a subject on which he is particularly fitted to speak. Dr. DONKIN'S official work of late years has been much concerned with such matters as crime, inebriety, and mental defect, and this fact led him to select for the matter of his discourse the evolution and inheritance of mental characters with special reference to the influence of heredity in the causation of anti-social conduct; and he has had an easy task in showing that such a choice of subject, so far from being alien to a Harveian oration, is peculiarly fitting to the commemoration of the great master who thought nothing in nature more marvellous than that law by which, to quote his own words, "the son is born like his parents, and virtues which ennoble and vices which degrade a race are sometimes passed on to descendants through a long series of years." The lucidity and conciseness with which Dr. DONKIN has treated this vast question will excuse us from all attempt to condense his remarks; but the salient lesson of his discourse may perhaps be dwelt upon briefly with advantage to our readers.

Dr. DONKIN'S address is essentially a plea for a more catholic spirit with regard to scientific methods of inquiry. As he rightly insists, we are nowadays in some danger of adopting a too exclusive attitude in this matter, and we are apt to pin our faith to some one particular form of investigation instead of following that comprehensive method which takes into account all authentic and relevant facts, by whatever way the knowledge of them may have been acquired. And no better proof of the soundness of this view could be furnished than the recent history of one of the subjects to which Dr. DONKIN refers, and on which, indeed, he speaks with exceptional authority. We allude to the study which it is now customary to designate by the term "criminology"—a hybrid term of barbarous sound which Dr. DONKIN reprobates by the gentle censure of inverted commas. The study of crime has necessarily attracted attention from the first institution of society, and theories of crime and conceptions of the nature and temperament of criminals are implicit in many of those primitive generalisations which have come down to us as proverbs. And from those early days down to the time of learned Congresses of Criminal Anthropology the question of the etiology of crime has been discussed with a great expenditure of zeal and industry and with extremely little practical result. And if we ask the reason of this unsatisfactory issue we shall find it in that tendency to narrow and one-sided inquiry which Dr. DONKIN so justly criticises. Of the earlier theories regarding the criminal individuality it is needless to speak; they made no pretence to a scientific origin. More instructive from our present point of view are those doctrines of later date which are associated in the popular mind with the conception of criminology, and which, as they are supposed to be the outcome of inductive investigation, are presented by their adherents as in a special degree scientific. These doctrines of hereditary criminality, which Dr. DONKIN stigmatises as "a mass of imperfect and unclassified observations linked together by untested hypotheses," are, surely, an excellent example of the dangers against which he seeks to warn us in biological and sociological inquiries, and the evils which they illustrate on a somewhat magnified scale are met with also in a less marked, and therefore more insidious, form in other investigations of a similar order. When we examine these doctrines more closely we are immediately struck by the fact that, despite their avowedly inductive origin, the hypotheses of a congenital criminal organisation are based on an *à priori* assumption of a kind with which some biologists have made us familiar in recent years. That assumption is to the effect that modes of social conduct can be reduced to the expression of simple inborn traits; the "criminal" is a law-breaker by virtue of his innate anti-social disposition, the "inebriate" drinks to excess because of an innate susceptibility to the charm of alcohol, and so on. This method of explaining criminal conduct—a method which we can hardly call original, for it was anticipated by MOLIÈRE'S doctor when he accounted for the action of opium by ascribing to it a *virtus dormitiva*—would not, perhaps, have gained acceptance had it been so crudely stated, but when it was presented with the support of an imposing array of anthropometric observations its inherent fallacies were disguised, and it took on an imposing scientific air because, as Dr. DONKIN points out, we are prone to attach exaggerated importance to the data ascertained by experiment or by the application of special methods of research, while we undervalue those facts which we can discover by the exercise of our intelligence and our unaided senses. We have, in fact, so thoroughly taken to heart HARVEY'S exhortation "to search out and study the secrets of nature by way of experiment" that we are in some danger of exalting this method into a fetich. Heaven forbid that we should belittle whole and excellent schools of hard and acute work; but we must try gallantly to relegate that work to its proper place.

Another lesson, and a lesson which Dr. DONKIN has been careful to inculcate throughout his discourse, is that we are perhaps too ready at the present time to ignore the influence

of the environment in determining the direction of individual development. This tendency, which the doctrine of hereditary criminality displays in an extreme form, is implicit in a great deal of that biological discussion of social problems which enjoys so wide a vogue nowadays. The biometrician with his mass statistics and the Mendelian with his pedigrees, however much they may be at variance on other matters, appear to be agreed not infrequently in assuming that the social value of the adult individual can be taken too completely as a measure of his germinal endowment. When we bear in mind how large a part gratuitous assumptions of the same sort played in the theories of LOMBROSO the analogy may perhaps inspire us with a distrust of such generalisations, doubly dangerous because they are offered to us as motives for immediate actions and abstentions which may have far-reaching effects on the well-being of the race. Meanwhile, we shall do well to remember that the study of the criminal by the methods which are now at length beginning to be adopted—that is to say, by the psychological examination of individual criminals—by no means confirms any view that the rôle of the environment is negligible; on the contrary, it tends more and more to show that, to quote the apt language of MANOUVRIER, in most instances the delinquent differs from the law-abiding citizen mainly in his acts and little in his aptitudes, and that criminal conduct is far more a result of unfavourable environment than of abnormal organisation. It does not, of course, follow that this is equally true of the relation of organisation and environment in other bio-social phenomena; but it is certain that we cannot accept the contrary view until we have confirmed it by applying to the examination of these phenomena the same method of individual study which, as has been so rightly urged by Mr. J. LIONEL TAYLER, is the essential foundation of sociological inquiry.

Anaphylaxis.

THE phenomenon of anaphylaxis or hypersensibility to serum or protein injections is one with important practical bearings in connexion with the treatment of disease in man by the injection of alien serums. The term "anaphylaxis" was originally introduced by RICHET as an antithesis to prophylaxis, and is in some sense a misnomer, since anaphylaxis may be of value to the organism as a protection. VON PIRQUET introduced another term—viz., "allergie"—to express the altered power of an organism to react to a foreign protein. The ordinary diagnostic tuberculin and mallein reactions are instances of anaphylaxis. No reaction is produced in normal persons by these substances in moderate doses, whereas in those suffering from tuberculosis or glanders a reaction is produced owing to the increased susceptibility. Experimental anaphylaxis can be readily studied in the guinea-pig owing to its sensitiveness to substances such as horse serum, white of egg, and milk. The so-called "serum disease" which sometimes occurs in man after the injection of horse serum was studied by VON PIRQUET and SCHICK, who suggested that the immunity given by vaccinia and other infections may be due to a power of rapid or immediate reaction acquired by the organism, and that the property of anaphylaxis, so far from being a danger, may sometimes be a factor in protection.

An interesting review of the literature of this subject was published in the *Archives of Internal Medicine* of June 15th, 1909, by Dr. JOHN F. ANDERSON and Dr. M. J. ROSENAU, who have in collaboration devoted much attention to the investigation of anaphylactic phenomena. We have recently received an interesting report of further researches upon this subject by Dr. ANDERSON and Dr. W. H. FROST.[1] They point out that DOERR and RUSS have introduced a method enabling a quantitative study of anaphylaxis to be carried out, and that they have demonstrated a definite quantitative relation between antigen and sensitive antibody. Dr. ANDERSON and Dr. FROST give details of their own experiments and arrive at some interesting deductions from them in regard to the nature of hypersusceptibility, anti-anaphylaxis, and immunity. They used horse serum and white of egg as antigens, and they studied especially the anaphylactic antibody, for which they have introduced the new term "allergin." They believe that hypersusceptibility to a foreign protein consists in an increase in the normal power of assimilating this protein, especially an increase in the rapidity of the reaction. This is due to the formation of a specific antibody demonstrable in the serum of sensitive guinea-pigs and in somatic tissues such as smooth muscle. It is also suggested that the action of this antibody upon its antigen is quantitative and is probably primarily proteolytic. Anaphylactic shock is in their opinion a disturbance of metabolic equilibrium rather than the effect of a specific toxic action. Anti-anaphylaxis is the condition which immediately succeeds anaphylactic shock in an anaphylactic animal, in which it is in a condition of immunity to anaphylactic shock from a further injection of the same antigen. Anti-anaphylaxis may, however, be induced by injection of antigen in repeated small doses. It is explained as due to saturation of the anaphylactic antibody with antigen. Anti-anaphylaxis is a temporary condition, which passes gradually into a condition of relative insusceptibility, which is distinguished as "immunity" proper. Anaphylaxis may be transferred passively to a normal guinea-pig by injection of serum from a sensitised animal. This passive transfer, as also the hereditary transmission of anaphylaxis, consists in a transfer of the anaphylactic antibody according to Dr. ANDERSON and Dr. FROST. They conceive anaphylaxis as a step toward immunity which is an increased capacity for safely and rapidly eliminating the specific antigen protein.

An interesting paper from Professor G. BILLARD, of Clermont-Ferrand, is published this week, in which he suggests that hay fever, asthma, nettle-rash, and the idiosyncrasy possessed by some people towards certain articles of diet are all manifestations of anaphylaxis. He gives details of a case in which he was able to trace the successive steps in the progress of the patient's condition from nasal catarrh to a bad attack of asthma. He believes also that some asthmatics are hereditarily anaphylactic. In regard to nettle-rash, he quotes a case of a young man who always developed nettle-rash after

[1] Studies upon Anaphylaxis. Bulletin No. 64, Hygienic Laboratory, Public Health and Marine Hospital Service of the United States, Washington, 1910.

eating pork. His serum injected in a guinea-pig induced a clear anaphylaxis towards pig's serum. The attacks of asthma induced by articles of diet Professor BILLARD explains in a similar manner to those induced by pollen, and to the urticaria induced by shellfish or similar articles of diet—viz., as manifestations of anaphylaxis. He sums up his views in the following sentence: "I am able to conclude that neuro-arthritics, and especially asthmatics and those predisposed to hay fever, are persons victims to anaphylaxia, either hereditary or acquired." His observations, though suggestive, hardly afford convincing proof of the thesis he champions, since the absolute experimental demonstration of the anaphylactic nature of some of the conditions he refers to is, as he admits, at present wanting. It is also noteworthy in this connexion that the majority of observers have failed to induce experimental anaphylaxis through the alimentary canal, the antigen protein apparently having to be given by subcutaneous, intravenous, or hypodermic injection to be successful. Until the possibility of successful production of anaphylaxis through the absorption of the antigen by the alimentary canal has been incontrovertibly established Professor BILLARD'S views must remain unconvincing.

It is difficult at the present time to determine the exact rôle of the phenomenon of anaphylaxis in the general process of immunity. As our knowledge of the reactive process of the body develops it becomes increasingly obvious that immunity is a highly complex process, and that the relative importance of humoral or chemical, and of phagocytic or cellular, reactions is difficult to appraise. The question of anaphylaxis in relation to immunity was discussed at some length by Dr. F. W. ANDREWES in the Croonian lectures, which were published in THE LANCET of June 25th, July 2nd, 9th, and 16th. He demonstrated that the phenomena of anaphylaxis are not entirely humoral, and that the leucocytes are profoundly affected during certain phases of the reaction between antigen and antibody. The initial leucopenia which occurs after the injection of living or dead bacteria or after the injection of antigen in an anaphylactic animal is, he maintains, an anaphylactic phenomenon. It is in effect an immunity reaction, and is, he further suggests, a more delicate test of the reaction between antigen and antibody than the occurrence of the clinical symptoms of anaphylactic shock. The dangerous and sometimes fatal nature of these symptoms seems difficult to interpret on the view that anaphylaxis is an immunity reaction, and therefore useful to the organism, but, as Dr. ANDREWES points out, under natural conditions it is highly improbable that so large doses of alien protein or of bacterial agents will suddenly gain entrance as those given under experimental conditions. His conclusion is worth quoting. "We must not," he says, "deny the right of the anaphylactic animal to be termed immune merely because we can make it ill or kill it by an artificial procedure which has no parallel in ordinary life." There can be little doubt that the property of anaphylaxis is one of great importance to the organism and that its careful study will yield valuable information and probably important practical applications. The literature of the subject is already considerable and its developments will be watched with interest by all who are engaged in the therapeutic applications of immunity reactions.

Bone-setting.

WE venture to deal somewhat plainly with certain utterances of Mr. W. T. STEAD in the *Review of Reviews* for October, and we are sure that he will not resent our plainness, for he has alluded to THE LANCET in epithets so uncomplimentary that he must have been seeking a straight reply. In the last number of the *Review of Reviews*, then, there is an account of the doings of a well-known bone-setter, and to his achievements in what Mr. STEAD terms a "hinterland of surgery," meaning, it would appear, a department of surgery which, formerly practised chiefly by persons described as "bone-setters," was prominently brought before the medical profession in our columns, 40 years ago, by Dr. WHARTON HOOD, who more recently, and shortly before his retirement from practice, published a treatise on the manner in which recent injuries should be dealt with, in order to avoid the occurrence of the conditions which he had previously shown the way to cure. We will not attempt to follow Mr. STEAD through a discussion in which a fertile imagination is drawn upon for an account of the position which we have assumed; but we may point out that the present support of Mr. H. A. BARKER is not more emphatic than that which he accorded, a few years ago, to Count MATTEI and variously coloured "electricities." There is no doubt that Mr. STEAD is very imaginative. We do not suggest that Mr. BARKER belongs to Count MATTEI'S category; and if it be true, as more trustworthy people than Mr. STEAD have said, that he is a skilful manipulator, we can only regret that he has not enjoyed the benefit of a professional education which would have shown him certain pitfalls to be avoided, and would have enabled him to turn his natural gifts to the best account. We do not feel sure whether the description of his achievements in Mr. STEAD'S journal is entirely his own, or whether it has been partially refracted in its passage through the medium of Mr. STEAD'S consciousness, but there is one part of it on which we feel inclined to comment. We are told that Mr. BARKER has "cured" 27,000 cases which, according to the methods of the "recognised practitioner," were incurable; that he has failed, or so it is implied, in 3000 more which he took under treatment; and that he "selected" the 30,000 from among "a much greater number" who were brought to him. He would be compelled to make a careful examination in order to decide that a given case was unsuitable for his methods; and he speaks of requiring from five to twenty manipulations for a single patient, not to mention the time needed "for the production of temporary anæsthesia." It is not too much to assume that every case, taking one with another, would occupy him for an hour. But Mr. BARKER has only been at work, according to Mr. STEAD, for nearly 20 years, so that recently he must have been very busy, almost busier than it is possible to conceive, as a simple sum in arithmetic will show. The neglect of the medical profession cannot have hurt him materially.

Turning to the essential conditions of the problem which the discussion on the merits or demerits of Mr. BARKER has brought forward, they are, in truth, sufficiently simple. What is known as "bone-setting" arose as an industry in certain thinly populated parts of England, largely among the dalesmen of the north, where medical or surgical aid was often difficult to procure, where the sports and labours of herdsmen and shepherds entailed considerable liability to injury; and where domestic medicine, supported by the sensations of the sufferer, prescribed that an injured part should be kept at rest, and not infrequently that it should be comforted by hot fomentations. The hot fomentations promoted a flow of arterial blood to the injured part; the quiescence of the muscles withdrew the force by which this blood would normally have been pushed on into the veins; extensive transudation of blood fluids occurred, and this transudation, as time went on, hardened and contracted into crippling adhesions. The muscles, wasted and weakened by quiescence, were no longer able to perform even their normal functions, were utterly unable to overcome the new resistance opposed to them, and resented by pain any effort to force them into renewed activity. The result was a fixed and useless joint or limb, until the bone-setter, by more or less skilful manipulation, ruptured the adhesions and restored mobility, with the consequence that the muscles, unless hopelessly atrophied, regained in time their normal vigour. The type of the whole matter is furnished by a sprained ankle, which, 50 years ago, was treated by rest and hot fomentations, and was justly regarded as a more serious injury than a broken leg, while to-day, treated by support and movement, it speedily recovers. The conditions tending to produce disability of joints and muscles received, unfortunately, a new lease of life in this country from a misinterpretation of the teachings of the late Mr. HILTON, whose famous prescription of rest for pain, too faithfully followed, has furnished hundreds of cases to the bone-setter. Those who followed Mr. HILTON'S recommendations were apt to forget that rest implies eventual atrophy of muscle, with consequent venous congestion and plastic effusions into the surrounding tissues; and that pain, arising from the fact that a weak muscle is called upon to exert itself, is not only as harmless as the pain of parturition, but is certain to bring about its own cure by the mere continuance of effort in disregard of it. The improved results now obtained in the treatment of fractures, which are largely due to Dr. WHARTON HOOD'S teaching and example, are mainly dependent upon rubbing to prevent stagnation of the venous current, and upon sufficient action of the muscles of the limb to preserve them from undue wasting during the period of reunion. The business of scientific surgery is not so much to become skilful in manipulations which ought not to be necessary as to treat injuries in such a way that prompt recovery may ensue, and that no manipulations will be required. The cases following injury in which the bone-setters achieve success will be found, on inquiry, to resolve themselves into two categories: those in which an injury, such as a rupture of muscular fibres, received during some active game had been originally treated by mere rest at home, under the belief that it would "soon get well," and those in which the natural desire for rest had been encouraged by some practitioner, who, in this respect, had suffered himself to remain somewhat in the rear of the modern developments of surgery. There is, in reality, no "hinterland," unless such a name can be given to a number of cases due to ineffective treatment of recent and comparatively trifling injuries, injuries of a class which has been rendered numerous by the modern devotion of youth to the pursuits of athleticism, and to the often untrained condition of those by whom these pursuits are undertaken.

Whether Mr. BARKER'S practical knowledge of anatomy, which appears, according to Mr. STEAD'S article, to have been gained independently of dissection, from the perusal of two excellent manuals, can be sufficient to furnish safe guidance in his manipulations, is a question highly interesting to his patients, but one which we do not propose to discuss. The point of chief importance to the profession is whether the supposed hinterland has any real existence other than as a residuum left behind by domestic medicine, or possibly, in some cases, by methods of treatment in which rest has been carried to excess, and the sensations of the patient indulged without due reference to the effect of the indulgence upon his permanent welfare. Nothing in Mr. STEAD'S words, convincing as he has tried to make them, leads us to suppose that we have taken up an illiberal attitude in this matter, or that bone-setters, individually or as a class, ought to be regarded as on the same scientific plane as fully qualified medical men. His article, to which he has invited our attention, ends with an appeal "made with the utmost confidence" to leading surgeons and others to constitute a committee of surgeons, whose names would command the respect of the public, to investigate Mr. BARKER'S methods. We think that Mr. STEAD'S utmost confidence may be betrayed, and that he himself has, not for the first time, written about what he does not understand.

Annotations.

"Ne quid nimis."

THE PRICE OF PROGRESS.

IT was a well-known custom amongst primitive peoples to assure the stability of any undertaking by the sacrifice of life. In the earliest times the life was human; in later and more merciful days an animal was substituted, and still later an image was used, or sometimes the shadow of a man was allowed to fall over the foundation trench, and was thereby symbolically buried, but in all these rites the sacrifice was voluntary. The human victim was sometimes willing, sometimes drugged, so as at least to be non-resistant, and the animal was bought with a price. Even now it is no uncommon thing in India to hear that a bridge or other structure will stand because certain lives have been sacrificed during the course of construction, and it is only too certain a fact that any advance in human invention is always accompanied by the payment of a heavy toll in human life. Only by this can the successors of the pioneers get the mastery over the new forces which have been discovered. To go no farther back than 15 years ago, the study of the Roentgen rays has led to the death or mutilation

of more than one investigator, but their sacrifices have not been in vain, for we have now learned much of the powers and the management of the new form of energy. But the most recent discovery, that of flying, is still in the stage of demanding life as a price, and during this year only we believe that 19 lives have been lost, while the motor-car, although now a common-place, has also a grim record behind it. Surely we may ask ourselves whether enough lives have not been sacrificed and whether needless risks are not being run. Wellman and his party have escaped destruction, but Chavez is dead, killed, if we may credit reports, on the practical completion of an undertaking into which he entered with great misgivings; Dickson is seriously injured. To pass to motor-cars, the Vanderbilt Cup race held on Long Island has resulted in four persons being killed, two of them competitors, and in 20 persons being injured. In this instance there was a competition, but an absolutely useless one—namely, a speed competition. Everybody nowadays knows that a motor-car can go at 60, 70, or even 80 or 90 miles an hour, so why demonstrate the fact again? The utility of the motor-car is beyond dispute, that of the aeroplane is still in a debateable stage, but in our opinion the time has arrived when useless competitions or exhibitions should be sternly put a stop to. We do not for one moment suggest that aeroplaning trials should be done away with. Unavoidable accidents may and probably will still occur and human lives may still be sacrificed in the pursuit and for the increase of knowledge, and the price, if necessary, will be willingly paid. But it is time that unnecessary risks should be forbidden. No goal was ever yet attained without the expenditure of toil and pain, the conquest of the air and the perfecting of rapid modes of locomotion may be necessary from a patriotic as well as a commercial point of view, and yet the counsel of an easy-going man of the world who was yet a true patriot is still good for us to remember:—

> Expertus vacuum Daedalus aera
> Pennis non homini datis;
> Perrupit Acheronta Herculeus labor;
> Nil mortalibus arduum est,
> Caelum ipsum petimus stultitia; neque
> Per nostrum patimur scelus
> Iracunda Jovem ponere fulmina.

Horace doubtless had something else in his mind when he wrote the word "scelus," but foolhardiness and unnecessary risks, run in many instances solely for gain, are no bad translation thereof.

HEART DISEASE IN THE HOME ARMY.

IN the *United Service Magazine* of Sept. 14th is an interesting article under the above heading by Dr. W. Hill Climo, lieutenant-colonel Army Medical Staff (retired). He asserts that heart disease in the British army has been for many years a byword and a reproach to the medical and military authorities, for it is associated in the public mind with the soldier's life and with service conditions which are believed to be detrimental to health. Dr. Climo maintains that these are erroneous views, but he believes that the fault does not rest so much with the public as it does elsewhere. He believes that to a certain extent the Army Medical Department is responsible, partly, he says, because for many years departmental opinion has been influenced by the fact that a post-mortem examination is made in the case of every death which occurs in a military hospital, so that every lesion of the heart and of the blood-vessels is recorded, whereas in the case of the civil population there is no means of obtaining like information. He proceeds to advance arguments in support of his belief that military service, instead of being a cause of heart disease, offers the best means for its prevention. In order to arrive at a conclusion statistical considerations naturally have to be carefully studied. On the one hand, the incidence of diseases of the heart and of diseases of the blood-vessels as occurring in soldiers has to be made out, and then the incidence of the same diseases amongst the general population must be ascertained. From the Army Medical Department reports the former information can be obtained, but it is practically impossible to so calculate the latter with any degree of exactitude. But by reference to the Registrar-General's annual returns of deaths the general mortality can be found for any particular year. In this way results can be arrived at that go a long way to substantiate Dr. Climo's contention. He shows (1) that, taking the whole population in England and Wales, there were 3110 more deaths from diseases of the heart and from diseases of the blood-vessels in 1907 than there were in 1906, while in 1906 the deaths from these diseases exceeded those in 1905 by 1968; (2) that the percentage of deaths in 1907 was 6 60 greater than in 1905; (3) that the combined death-rate of diseases of the heart and of diseases of the blood-vessels is the greatest of any group of diseases, and is at the present time only a little less than one-sixth of the total mortality from all causes; (4) that the death-rate in the army from these diseases is decreasing with a corresponding number of invalids, whilst the rejections on enlistment, with fluctuations, show a progressive increase (this statement is founded on statistical evidence); and finally, (5) that the services of France and Germany, the two countries which have adopted universal military service for the longest period, have of all armies the lowest admission- and death-rates for cardiac affections. Dr. Climo deals mainly with statistics, but there are some clinical points which have a bearing on heart disease in the army; for instance, diseases of the blood-vessels, aneurysms particularly, are of syphilitic origin, and it would be interesting to obtain observations as to the incidence of aneurysm in relation to that of syphilis amongst soldiers. The question discussed in the article under consideration is an important one, and Dr. Climo's suggestion that an "inquiry should be made by the Army Medical Department in association with the General Staff of the Army" is one which should receive attention.

CAN FISH CONVEY THE BACILLUS OF CHOLERA?

TO answer this question, Professor Gosio of Rome, the State bacteriologist, has begun a series of observations on the Apulian and Neapolitan littoral, a torpedo-boat having been placed at his service by the Admiralty, with all the resources of his office, in *personnel* and equipment, on board. That typhoid fever can be conveyed by fish, particularly by the *frutta di mare* (shell-fish) so largely consumed on the Italian sea-board, is a well-authenticated fact. Sewage still finds its way into those waters, and the oyster dredged off Santa Lucia is notorious as a cause of gastro-enteritis. So common, in fact, is intestinal disturbance, in the late summer and early autumn, among the Neapolitans with whom at that season "la zuppa marinara" and fish diet generally are in special favour, that, when the cholera appeared three weeks ago, its presence was masked by the symptoms all too familiar among the consumers of such fare—the initial vomiting and abdominal malaise, characteristic of the Asiatic disease, being vaguely set down to the "sturbi intestinali" endemic before and after the dog-days. Imported from the Russian shores of the Black Sea, the cholera numbered many victims at the Apulian ports, and their dejections, whether on shipboard or on the littoral, may have passed into the digestive apparatus of the fish—the crustacea, in particular—with the possible multiplication of the "vibrioni colerici specifici." Now, says Professor Gosio,

"the problem before us is to ascertain whether, having effected their way into the intestine of the fish, the said 'vibrioni' multiply in large numbers? Again, in what other fish, besides the molluscs, do they seem to find a lodgment? And, further, do they take most kindly to migratory fish, when they would constitute a serious danger by transporting the infection to a distance?" Professor Gosio adds that, in the process of cooking, and in frying rather than in boiling, the cholera bacillus may be rendered innocuous; but no one familiar with the perfunctory cuisine of the Neapolitan poor will place much reliance on this safeguard. Besides, the oyster, the most suspected of the "frutta di mare," is almost invariably eaten raw. Professor Gosio's researches come not an hour too soon and their results are awaited with interest, not only by the pathologist, but by the public, the northern section of it in particular, which seeks health and warmth and distraction in the sun-traps of Italia Meridionale.

ENGLISH URBAN MORTALITY IN THE PAST SUMMER.

UNTIL the results of next year's census are known medical officers of health, and all interested in public health, are practically bound to accept the vital statistics issued by the Registrar-General as the best available test of local sanitary condition, although these statistics are hypothetically calculated on estimates of population based on the rates of increase or decrease that prevailed during the ten years ending in 1901. There are many undoubtedly good grounds for the opinion that at the present time the populations of our large towns (residing within their arbitrary boundaries), taken generally, and of London in particular, are by the official method of estimation considerably over-estimated, resulting in the under statement of their current annual rates of mortality and in the exaggeration of the persistent decline of their birth-rates. Some of the medical officers of health of our largest towns express in their reports a conviction that the official estimates considerably over-state the true populations of their sanitary districts, but, failing any more trustworthy method of estimate (in the absence of a quinquennial census), they naturally accept the official estimates, which imply a too favourable test of the sanitary condition of the over-estimated towns. As it is, however, quite possible that by the official method the present population of some of our large towns may be under-estimated, it may be assumed that the value of official statistics relating to the 77 largest English towns, in the aggregate, is not seriously affected by the want of more accurate information as to their present population. The official estimate of the population of these 77 towns, in the middle of this year, is very close upon 17 millions. Accepting this estimate, the 13 weekly returns issued by the Registrar-General during the three summer months of July, August, and September last show that the annual rate of mortality in the 77 towns during that period was equal to 11·8 per 1000, against 13·4 during the corresponding periods of the four years 1906–09 in the 76 towns to which the official reports related in those years. These figures imply that the death-rate in our largest towns during the past summer was no less than 12 per cent. below the mean rate in the four preceding summer quarters. It is satisfactory to feel assured that, after full allowance for the more than probable over-estimate of the population of these towns, the official mortality statistics indicate a real and substantial improvement in the health condition of our largest urban sanitary districts. Using the same official estimate of population, it appears that the mean annual birth-rate in the 77 towns during the three recent summer months was equal to 24·7 per 1000, against 26·5, 26·9, and 25·3 respectively in the three preceding summer quarters; thus it may safely be assumed that the urban birth-rate continues to decline. We are fortunately able to measure the recent rate of infant mortality free from the disturbing factor of untrustworthy estimates of population. During the 13 weeks of the past summer quarter, ending on the 1st inst., the deaths of infants under one year of age registered in the 77 largest English towns were equal to 113 per 1000 of the births registered in the same period, against 109 in the corresponding period of 1907, 145 in 1908, and 119 in 1909. Thus the rate of infant mortality during the past summer in these large towns was 11 per 1000 below the mean rate in the three preceding summer quarters, showing a decline of almost 10 per cent. It cannot be doubted that the recent awakening of the public conscience respecting the waste of infant life, and the simultaneous weakening of later child life by neglect, ignorance, and sanitary shortcoming, is already yielding substantial results, as the decline in the rate of infant mortality is now being persistently maintained. The death-rate of infants under one year of age during the first nine months of this year in the 77 largest English towns was equal to 108 per 1000 registered births, against 119, the mean rate of infant mortality in these towns in the corresponding periods of the three preceding years, 1907–09. This encouraging result of increased and sustained action by sanitary authorities, in order to cope with the evil of excessive infant mortality, should stimulate to further action the authorities of those towns in which the excess of infant mortality does not at present show the average proportion of this encouraging reduction.

PROFUSE HÆMATURIA THE FIRST SYMPTOM OF HYPERTROPHY OF THE PROSTATE.

IT is well known that hæmaturia may be due to prostatic hypertrophy, but profuse hæmaturia as the first symptom of the disease is a rarity. In the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* M. E. Loumeau has reported the following case. A man, aged 46 years, who now lived a sober, regular life, and whose previous illnesses consisted of a transient attack of gonorrhœa at the age of 21 years and a mild attack of syphilis, which was well treated, at the age of 25 years, noticed with surprise on Feb. 12th, 1910, that the first urine passed in the morning had a slightly rosy tinge. This colour deepened progressively until the morning of the 17th, when the urine was distinctly bloody. During the day the hæmaturia became still more marked and large clots were passed, causing micturition to be more and more difficult and painful. In the afternoon M. Loumeau saw the patient in consultation. He was pale and uneasy, and was passing reddish-purple urine. A No. 18 bent (*béquille*) catheter was easily passed and much liquid and coagulated blood was evacuated from the bladder, which was then washed out with warm boric lotion until blood ceased to flow from the catheter. Rectal examination showed the presence of a doughy mass in the bladder. In consequence of the spontaneity and abundance of the hæmaturia, which was not preceded by any renal colic, the mass was thought to be a tumour. The intensity of the hæmorrhage rendered it impossible to verify the diagnosis with the cystoscope. About midnight the bladder became distended with clots which could not be passed. Catheterism was attempted by a practitioner, but he could not pass an obstacle deep in the urethra, and M. Loumeau was again summoned. He found the patient in great pain from the retention, and the bedclothes soaked by the uninterrupted flow of blood. A No. 20 bent cathether was passed, after momentary arrest due to slight urethral spasm, and the patient was relieved. The catheter was retained in the bladder. On the 18th the hæmaturia was unabated, and as it had proved intractable to medical treatment and threatened the patient's life M. Loumeau

decided to operate at once. He performed laparotomy under chloroform in Trendelenburg's position. A large opening was made in the bladder and much blood and blackish clots were removed, but no trace of a tumour or ulcer could be found. A citrine fluid was emitted by the ureters, which showed the integrity of the kidneys. The mucous membrane of the bladder was much congested in its whole extent, raised by large sinuous turgescent veins, and coated by an abundant serous transudation. Evidently the mass taken before operation for a tumour consisted of clots. The wound was sutured, drainage-tubes being inserted. For some days drainage was maintained. Recovery was uninterrupted and the hæmaturia ceased. What was the source of the hæmorrhage? For eight years the patient had noticed some difficulty in beginning micturition, and for some months micturition was frequent and painful in the morning. Though the hæmaturia ceased after the cystotomy the urine remained a little turbid, and during the night micturition was difficult and took place twice or thrice. Moreover, there was residual urine which varied in amount between 20 and 100 grammes. After complete emptying of the bladder with the catheter rectal examination showed two indurated nodules in the prostate of the size of an olive. Evidently the hæmaturia was the first sign of a slight and unsuspected hypertrophy of the prostate. It was presumably due to congestion developed around the nodules, which apparently were adenomata. The congestion extended to the whole of the vesical mucous membrane. M. Loumeau suggests that the prostatic hypertrophy was due to chronic prostatitis which was a sequel to the attack of gonorrhœa. The case also illustrates a fact which he has often observed—the onset of prostatic hypertrophy before the age of 50 years, the age given by writers. At this age difficulty in emptying the bladder may be first observed, but the hypertrophy of the prostate must have preceded this by some years.

ULSTER AND EMBASSIES TO CHINA.

THE freedom of the city of Belfast was recently conferred upon Sir John Jordan, K.C.B., His Majesty's present representative at Peking, and the ceremony was the occasion for the appearance of an interesting article in *The Northern Whig* of Sept. 28th from the pen of Sir John Byers dealing with the careers of three eminent Ulster men who were ambassadors to China. Sir John Byers is interested in all matters that belong to the history of Belfast and the province of which it is the capital, so that it was only natural that he should draw the attention of his fellow citizens to the predecessors of the distinguished man whom the city was honouring. Those predecessors were George Macartney, afterwards Earl Macartney; and Henry Pottinger, afterwards Sir Henry Pottinger. Macartney, who was sent out in 1792 as our first ambassador, was the great-grandson of "Black George Macartney," who went to Belfast from Scotland between 1642 and 1649. He became chief magistrate, or "Sovereign" as the title then was, and he should be held in honour by all medical men, for it was through his instrumentality that Belfast obtained a supply of "good and wholesome water"; for, as he mentioned in a proclamation dated July 29th, 1678, "the River which runneth through the Town is very much defiled and abused ..... whereby the water is made altogether unfit for the use of man in meat and drink." Even Belfast of to-day may remember these words with profit. His distinguished descendant's mission, though not successful in establishing a permanent resident at the court of Peking, yet brought about a prolonged period of tranquillity for commercial transactions. After his return he held other important posts, and died in 1806, leaving no heir. The name of Macartney, however, still has an honourable connexion with China in the person of Sir Halliday Macartney, who is councillor to the Chinese Legation in London, and, moreover, a medical man. Pottinger, who is the second on Sir John Byers's list, was appointed Envoy to China in 1840, and it was owing to his labours that the diplomatic victory was won which included the cession of Hong-Kong and the opening of the five treaty ports. As to Sir John Jordan, the present representative at Peking, his work is his best description, and well might Sir John Byers say of him that "he adds to the roll of the honorary burgesses of the city the name of one of the most distinguished Ulstermen of the present period."

THE SUPPLY OF DIPHTHERIA ANTITOXIN BY LOCAL AUTHORITIES.

IT is quite unnecessary to discuss the value of the antitoxin treatment of diphtheria. It has long passed the experimental stage, and those who neglected to use it in cases of diphtheria would lay themselves open to serious chances of scientific criticism. But, nevertheless, there are grounds for believing that antitoxin, for one reason or another, is not always administered as early as could be wished, and that it is not employed as a prophylactic in invaded houses with the routine regularity which preventive medicine demands. We have often, in reviewing the annual reports of medical officers of health, quoted comments indicating the frequency with which cases of diphtheria arrive at an isolation hospital without having already had the advantage of antitoxin inoculation, even although such cases had been ill for several days. Indeed, so frequent are these occurrences that in certain instances medical officers of health have themselves had antitoxin administered when notified cases of this disease have been visited by the health officers and proper treatment had not yet been applied. This delay in the administration of antitoxin is due partly to the want of facilities for prompt bacterioscopic examination and partly to difficulties in obtaining supplies. It may also be due in some measure to the question of expense. These facts have been so obvious to many sanitary authorities that they have themselves obtained a supply of the antitoxin for the use of local medical practitioners upon patients whose means were small, and within recent years large quantities of diphtheria antitoxin have been thus employed. It appears, however, that there have been legal difficulties in the way of this municipal provision of antitoxin, more especially so in its employment from a curative standpoint, and with a view of placing the matter on a satisfactory basis, both curatively and prophylactically, the Local Government Board has recently issued an Order authorising the provision of antitoxin in both these senses. In the circular letter which accompanied this Order the Board drew attention to the fact that the free provision of diphtheria antitoxin was in no sense to be regarded as a substitute for isolation in hospital, and that the prompt administration of antitoxin before the patient was removed might go far to prevent the attack from proving fatal. It is clear, we think, that the vast majority of local authorities throughout the country will welcome this provision for lessening the fatality rate and prevalence of this fatal malady, but Mr. F. W. Alexander, the medical officer of health of Poplar, draws attention in a recent report to an aspect of the question which should not pass unnoticed. In September, 1907, the sanitary committee of this metropolitan borough presented a report to the council emphasising the enormous advantages of antitoxin treatment as shown by figures derived from the Metropolitan Asylums Board and other statistics. The committee also expressed the opinion that in view of the loss, inconvenience, and suffering occasioned by the erroneous notification and removal of

patients not suffering from the disease notified, diphtheria antitoxin should be supplied for use pending the report of the bacteriological examination in cases where such provision cannot be otherwise made. But the council, after consideration of the report, arrived at the conclusion that it could "not enter into competition on an unfair basis with purveyors of drugs and related preparations," and it emphatically refused "to relieve medical practitioners of their natural responsibilities." This expression of opinion raises incidentally some rather far-reaching issues—so far-reaching that we can only briefly indicate them here. It may suggest, for instance, that the arrangements for medical treatment amongst the poor are so unsatisfactory that drugs and kindred preparations cannot, for the payment available, always be administered; and it might, of course, be contended that all sera and cultures not easily obtainable should be provided for the poorer classes by the sanitary authorities. It may reasonably be urged that such municipal action would only be justifiable in dealing with preventable disease; but here, again, we feel ourselves on the horns of a dilemma, since nearly all diseases may be regarded as more or less preventable. For example, in the case of acute rheumatism the early administration of the specific drugs in proper amount may prevent the dreaded complications, and a similar line of argument may be employed as regards venereal diseases. Probably the answer to these problems may be found when the subject of the relation of the State to the medical profession, which is now in the melting-pot, is receiving final consideration, but in the meantime the poorer classes must have antitoxin in their need, and at the present moment the only feasible method of securing its prompt administration appears to be through the agency of the sanitary authorities.

THE MEMORIAL TO THE LATE MISS FLORENCE NIGHTINGALE AT LIVERPOOL: A REGRETTABLE DIVISION OF OPINION.

THE public meeting held in the Liverpool Town-hall on Oct. 13th, at the invitation of the Lord Mayor, to inaugurate a memorial to perpetuate the memory of the late Miss Florence Nightingale disclosed considerable differences of opinion as to the form the memorial should take. Hitherto it had been the custom at such a meeting solely to decide upon the establishment of a memorial fund in honour of a distinguished person, the direction which the memorial should assume being delegated to a committee of the citizens present. On this occasion a departure from custom was witnessed. The committee of the Queen Victoria District Nursing Association, which body desires to build an additional district nurses' home (stated to be urgently needed), approached the Lord Mayor with a scheme, asking that the memorial should take the form of a seventh district nurses' home, the funds to be applied to its erection and maintenance. No one would deny that what the association seeks to do is very proper and useful, but the claims of nurses in need of pecuniary assistance to the benefits of a memorial fund to their dead leader began to receive attention prior to the date of the town-hall meeting. Letters appeared in the columns of the local press pointing out the needs of many nurses of advancing years, and warmly advocating that the funds of the proposed memorial should be applied in the direction of their necessities. In the face of this correspondence it would have been perhaps well if the Lord Mayor had fallen back upon precedents and had accepted the suggestion of Mr. J. E. Sampson, the city coroner, to refer the details of the memorial fund to a committee of those present at the meeting. This, however, he decided not to do, but put to the general meeting a proposal of the Rev. T. W. M. Lund for the establishment of a memorial fund to be applied in the direction of a "home of rest" or a pension fund for necessitous nurses. This proposal was lost by the bare margin of 2 votes, Sir James Barr and others warmly taking up the cudgels on behalf of the poor nurses. A majority of 2 votes, therefore, stands in favour of the scheme to which Mr. Lund's was an amendment—viz, of founding a seventh district nurses' home. This vote cannot be a matter of congratulation to the committee of the Queen Victoria District Nursing Association, and there is a widely expressed fear that a chilling effect may result on the liberality of the citizens of Liverpool. May there not be yet time to reconsider the position and to allow the needs of the nurses at least to be met by a share in the benefits of the Florence Nightingale Memorial?

SYPHILIS AND MUSCULAR ATROPHY.

OUR nosological conception of that commonest of spinal cord diseases, tabes dorsalis, has been undergoing important changes in recent years. The discovery of the organism of syphilis has sensibly modified our ideas on the whole question of syphilitic infection. If we trace the steps whereby the syphilitic virus establishes its hold on the medullary nervous system, they are found to be constituted somewhat as follows. In a great number of cases secondary syphilis is accompanied by a mononuclear lymphocytosis of the cerebro-spinal fluid—the clinical expression of which is headache—a meningeal reaction on which mercury exerts a suppressing influence. The histological processes in this meningeal reaction of secondary syphilis have been carefully studied by Sezary. He has found subarachnoid infiltrations more particularly on the posterior aspect of the cord and in the lumbar region, vascular lesions, and interstitial changes in the posterior roots and posterior root ganglia. We know that this meningeal condition may be entirely unsuspected, to be discovered only by rachicentesis, or that its sole clinical manifestation, according to Babinski and Charpentier, may be the sign of Argyll Robertson. Should the syphilitic toxin maintain its hold the development of syphilitic meningo-myelitis is most likely to occur. Some of its varieties present a considerable resemblance to tabes; many instances of "pseudo-tabes syphilitica" have been recorded; rarely, symptoms both of tabes and syphilitic meningo-myelitis may occur together. The distance in time which often elapses between the syphilitic infection and the appearance of tabetic symptoms can no longer be justifiably advanced as a criterion to distinguish tabes from other forms of medullary syphilis, nor, indeed, can the difference in the response of the two types to antispecific treatment be so considered. Fournier's "parasyphilis" is losing somewhat of its significance. Syphilis in its attack on the nervous system may reveal itself in most diverse ways, from acute meningitis to general paralysis. We have reached a period when the neurologist is thinking less of systematised diseases and more of clinical syndromes. These considerations apply forcibly to the question of muscular atrophy of spinal origin, as is clearly demonstrated by M. Felix Rose and M. Henri Rendu in *La Semaine Médicale* of May 11th. The Aran-Duchenne type of amyotrophy is not a disease, that is, not a nosological entity, but a clinical syndrome. It may arise in the course of tabes dorsalis, and it may develop by itself where the sole preceding etiological factor is syphilis. In fact, Léri, struck with the frequency with which syphilitic antecedents are noted in the various cases of progressive muscular atrophy of this type scattered through medical literature, goes so far as to say that the commonest cause of the syndrome is syphilitic meningo-myelitis. Pathological evidence is not wanting to confirm this view of many cases of spinal amyotrophy. The occurrence of chronic anterior poliomyelitis of syphilitic

origin is a fact not perhaps sufficiently realised. Tabetic muscular atrophy (that is, of the Aran-Duchenne type) is indistinguishable from that of medullary syphilis. Further, muscular atrophy may appear in the course of general paralysis. The why and the wherefore of the variability in the nervous sequelæ of syphilis is still quite unknown; why tabes should appear in one case and meningo-myelitis in another, why muscular atrophy should sometimes be present, sometimes absent, are problems for the future to decide. The view the authors take is that certain syphilitic lesions, notably meningo-myelitis, alter in the course of their evolution; they lose their specific characteristics and tend to give place to chronic lesions, which in their turn produce definite cord changes, by relative ischæmia or otherwise, such as atrophy of anterior horn motor cells.

A CASE OF LEPROSY TRACEABLE TO INOCULATION.

IN the *South African Medical Record* of Sept. 10th appears an interesting note by Dr. W. Russell. A healthy boy of 14, the son of a Dutch farmer and an Englishwoman, cut his foot with broken glass while bathing. The wound bled freely, and a native suggested the application of tobacco as a styptic, offering a piece which he was chewing at the time. This was bandaged to the wound with a handkerchief and kept on in this way for three days, when the wound seemed to have healed almost completely. During the boy's life at a boarding school the wound kept on breaking out every two or three months for about three years, so that a medical man who saw him, suspecting necrosis of bone, made an incision and scraped the wound. About this time nasal and pharyngeal symptoms appeared and he become hoarse; a rash developed, and the boy became so unwell that his studies were discontinued. He was troubled by fainting attacks and shooting pains in the limbs. After nine months' treatment for syphilis, a diagnosis in which several practitioners concurred, he was taken to Dr. Russell, who found him well nourished, speaking with a husky voice, but showing no pharyngeal ulceration, though the mucous membrane was very congested, and there was a nasal discharge. The wound had healed, no rash was seen, but his hair was coming out. Under further treatment for syphilis he became worse, and Dr. Russell found bacillus lepræ in the nasal secretion. During the following six months the facies of leprosy developed, the hair continued to come out, anæsthetic patches appeared on the body, and an ulcer formed on the right foot, with painful fissures between the toes. He died about 11 years after the inoculation, which was attributed to the tobacco dressing, inquiry showing that the native from whose mouth the plug came was a leper, who had died about four years after his act of mistaken kindness. Moreover, there was no other conceivable source of infection.

THE OILS, FATS, AND WAXES OF THE PHARMACOPŒIA.

MUCH progress has been made since the publication of the 1898 edition of the British Pharmacopœia in the analytical examination of the official oils, fats, and waxes, and the data which have been collected will be of considerable value to the compilers of the next edition. An evening meeting of the Pharmaceutical Society on Oct. 11th was devoted to the consideration of this subject, and Mr. F. C. J. Bird and Mr. E. W. Lucas read communications in which they suggested a basis for the monographs on oils, fats, and waxes for the next Pharmacopœia. They expressed the opinion that the tests in the official monographs should be as comprehensive as possible, since much trouble has been caused in the past owing to the insufficiency of the official tests as a means of ensuring that degree of purity necessary in articles required for medicinal use. They suggest the introduction of methods which, although long practised by analytical chemists, have as yet found no place in the British Pharmacopœia in connexion with the fixed oils and fats. The new analytical figures which these observers think it desirable to introduce are the saponification value, the iodine value, the percentage of free acid, the percentage of unsaponifiable matter, and the refractive index. Mr. Bird and Mr. Lucas, who were requested by the Committee of Reference in Pharmacy to the Pharmacopœia Committee of the General Medical Council, of which they are members, to investigate this subject, submit the suggestions for professional criticism. It may be added that they take the view that the tests of the Pharmacopœia should be so framed that when applied in conjunction with the definition in the context they should make it perfectly certain that the article under examination is of the quality and purity intended by the Pharmacopœia for use in medicine. They regard the Pharmacopœia as a means of ascertaining the suitability of the articles enumerated therein for use in the dispensing of prescriptions and the preparation of medicines, and it is from this standpoint alone that they have drafted the suggested monographs.

SCARES.

IT is difficult to understand why some of our newspapers are so eager to become the bearers of evil tidings to the public, and why they should hasten to announce the bad news before the facts have been properly verified. Last week many persons were startled to find in their morning paper a statement headed in large type "Cholera in London." On looking more closely into the matter we found that the basis for this assertion was the occurrence of a fatal case of gastro-enteritis in a London hospital, the existence of cholera, however, being subsequently disproved by bacterioscopic investigation. Nevertheless, a thrill of needless fear must have been experienced by many nervous people who have a dread of exotic infection. A couple of days later huge posters were issued by a daily paper announcing in large letters "Plague in the Thames." Upon inquiry we discovered that this alarming announcement related to a single ship-borne case of plague, landed from a Bombay steamer, safely isolated by the officers of the London port sanitary authority in its hospital at Denton, from which there could be little possibility of extension of the infection outside. Almost simultaneously another paragraph appeared with the disturbing intelligence of an "Outbreak of Spotted Fever." Upon investigation we found that the so-called outbreak comprised in this instance also only a single case. The use of the term "spotted" fever instead of cerebro-spinal fever is no doubt attended with more alarm, as any illness with an eruption is greatly dreaded. And the use of the term "spotted" may be wrong, since in the majority of cases, in this country at least, the patients attacked by cerebro-spinal fever exhibit no spots at all. It is a misuse of the power of the press to employ it in curdling the blood or making the flesh of nervous or ignorant people to creep. It is, we know, urged in defence that the press must "put the public on their guard." But there can be no excuse for announcing cholera in London when there is none. It cannot be said that if plague has arrived in the Thames the individual readers of the announcement can as a result take any practical steps by themselves to escape from the disease. Rather must they rely upon the sanitary authorities, local and central, to protect them from imported infections. To produce panic in the public mind is not the way, in our opinion, to prevent the spread of exotic disease; and the insertion in newspapers of

alarming headlines based upon very slender foundations seems to be both unnecessary and improper from the medical point of view.

SERO-THERAPEUTIC TREATMENT IN OPHTHALMIC AFFECTIONS.

AN article with the above heading appears in the October number of *La Clinique Ophtalmologique* from the pen of Dr. Alexandroff, who, as ophthalmic surgeon to the "Eugenie" Hospital of Ajaccio, has had large experience. He only gives the results of those cases in which he has followed out this method of treatment for a period sufficient to form definite conclusions in regard to its success or failure in infectious cases. Dr. Alexandroff has invariably employed the anti-diphtheritic serum of M. Roux and has always practised the simple hypodermic proceeding. He has never used more than four injections of 10 cubic centimetres each of the fluid as an injection. He has never seen any untoward accident from the use of the serum. In almost every case he has obtained favourable results, and in some cases the results have been phenomenal, as in the following instance. A lady, aged 42 years, whose state of general health was perfect, consulted Dr. Alexandroff with very alarming symptoms. She had been suffering from severe neuralgia arising from disease of a canine tooth, when after using human milk as a collyrium the eye on the same side became red and extremely painful. On examination it was found that there was a serpiginous ulcer with hypopyon. The healthy condition of the lacrymal passages, with the unusual position of the ulcer, which was seated at the upper border of the cornea near the limbus, led him to conclude that there had been an ulcer of dental origin which had become infected by the milk. The treatment adopted was removal of the root of the canine tooth and three cauterisations, in spite of which the ulcer continued to advance. The upper two-thirds of the cornea became opaque, and the hypopyon filled a large part of the anterior chamber; perforation seemed to be imminent, and a Saemisch's keratotomy was proposed, but was strongly objected to by the patient. Under these conditions, although up to that time sceptical, Dr. Alexandroff bethought himself of treatment by serotherapy, and requested his colleague Dr. Pompeani to make an injection of 10 cubic centimetres. The next day the patient failed to present herself, and Dr. Alexandroff supposed that the eye was lost, and was agreeably surprised when on the day following she appeared in good spirits, stating that she had slept well for the first time for 12 nights. Upon examining the eye the hypopyon was in great part absorbed, the cornea was clearing, and the ulcer presented a more wholesome aspect. After two more injections recovery was complete. Several other cases are reported by Dr. Alexandroff: one of a child with infective conjunctivitis, one of a patient suffering from ague, one of keratitis after an operation for cataract, and one of an ulcer of the cornea after a blow with a stone, in all of which a satisfactory result was obtained.

WE hear with regret that the death of Dr. Sydney Ringer has taken place at his country residence at Lastingham, Yorkshire. Dr. Ringer, who was 76 years of age, was a Fellow of the Royal Society, Emeritus Professor of Medicine at University College and consulting physician to the hospital, and the author of the well-known "Handbook of Therapeutics."

ACCORDING to statistics contained in the last report of the Commissioners of Customs and Excise, the net receipts from the Medicine Stamp Duty during the years 1901–10 were as follow: 1901, £297,480; 1902, £306,337; 1903, £333,371; 1904, £323,446; 1905, £331,439; 1906, £324,112; 1907, £327,106; 1908, £334,142; 1909, £315,489; 1910, £313,114.

THE opening lecture of the North-East London Post-graduate College will be delivered at the Prince of Wales's General Hospital, Tottenham, N., on Thursday, Oct. 27th, at 4.30 P.M., by Sir T. Lauder Brunton. Any member of the profession desiring to attend the lecture is asked to communicate his wish to the Dean of the school at the hospital.

THE Page May Memorial Lectures in Physiology will be delivered by Professor C. S. Sherrington at University College, London, on Oct. 24th and 25th, Nov. 7th and 8th, and Nov. 28th and 29th, at 4.30 P.M.

TOWN-PLANNING CONFERENCE AND EXHIBITION.

WHATEVER may be thought of the debates at the Town-Planning Conference or of the exhibtion of drawings and models held at the Royal Academy from Oct. 10th to 22nd, the mere fact that such a conference and exhibition have taken place is a most hopeful sign of the times. It does seem as if we were awakening as a nation from lethargy, but it is sad, particularly at the exhibition, to find that even in our own country nearly all the wall space was covered with maps and drawings of what had been done by other nations. Yet that we should have had the courage to expose ourselves to such unflattering comparisons is surely a wholesome indication of a vigorous desire to set our own house in order. The position was very clearly put by the President of the Local Government Board at the opening of the Conference. Every 15 years, he said, some 500,000 acres of agricultural land were converted into building land. But as all this building is left to mere chance the municipal corporations, at their last annual gathering, estimated that during the recent 30 years from £14,000,000 to £15,000,000 had been spent in undoing mistakes that should never have been committed. For instance, as Mr. Raymond Unwin subsequently pointed out, it may generally be noted that in and near towns the land on either side of railway lines or canals is covered with cottages and dwellings. Obviously these are the sites that should be occupied by factories and workshops, thus reducing the traffic of merchandise through residential streets. But in building towns no one had given a thought to the needs of traffic and its probable developments. Even to-day 5000 houses are being built or rebuilt in London during the course of a year with very little regard to the present and future requirements of traffic. In this respect one of the few things shown by English exhibitors is a bold scheme for removing Charing Cross Station to the Surrey side. A monumental approach would be made by bridging the Thames with a broad roadway protected on each side by a graceful colonnade where people could shop in rainy weather on the model of the rue de Rivoli in Paris. But if, in Paris, this is convenient for the purchaser, the shops are insufficiently lighted by the direct rays of sunlight and have even less air and light at the back. On the proposed bridge the shops at the back would have a splendid look-out over the Thames, and would be much more healthy than the shops, for instance, in the Strand.

Even the most enthusiastic advocates of town planning have not yet fully appreciated the question of direct rays of sunlight. Obviously, in a rainy climate, the street colonnade like that of the rue de Rivoli, reproduced in London in front of the Hotel Ritz, is most convenient, and it lends itself to handsome architectural designs. But, from the health point of view, it cannot be approved unless there is ample compensation of unimpeded rays of light in the rear of the premises, and such would be the case on a bridge. In this respect we are glad to see M. A. Augustin Rey is again to the forefront as an apostle of light. He shows astronomical observations affecting ten of the largest towns, including London, with a total population of 25,000,000, all in temperate climates and with houses of from two to six storeys high. His obvious teaching is that we have

not only to reckon with the width of the street: houses that have their axis directed from north to south will receive the greatest number of luminous rays on their east and west walls, and will be more healthy than those in streets running west to east. The latter streets must, he suggests, be much wider. This question of the width of streets being modified according to the direction in which they run, so that the houses may receive an equal share of sunshine, is not yet included in town-planning schemes, and it deserves very careful consideration.

Town planning, however, is not simply a question of light and air, space, and drainage. Sanitary engineering plays a very important part, but even from the public health point of view art is most essential. We demand the city beautiful not merely because a thing of beauty is a joy for ever, but because joy is essentially a wholesome feeling. Beauty is preventive and curative medicine. It helps to make us happy and therefore to keep us in good health, while if, unfortunately, sickness has successfully invaded our system, we are much more likely to find the necessary vitality to recover in the contemplation of things that are graceful, pleasing, and inspiring than in the contemplation of drab ugliness. Thus, from whatever aspect the question may be viewed, we must congratulate ourselves on the successful gathering of the Town-Planning Conference. We wish that at the exhibition there had been more ample explanations given and better measures taken to interest the general public. It is the general public that will have to pay for town improvements, and, unless it understands, it is apt not merely to grumble but to vote against the promotion of much-needed reforms. Professor G. H. Reilly said that for the former "benevolent despotism of the great landlords ..... we must substitute an organised democracy." That being so, no opportunity should be lost of educating that democracy.

We have made no attempt to review the various utterances of many distinguished persons upon the different subjects that come under the heading of town-planning, but the movement is so essentially one bound up in the closest way with the public health that a brief record of its progress is necessary.

FORTY-SIXTH ANNUAL REPORT OF THE REGISTRAR-GENERAL FOR IRELAND.

THIS report contains a detailed account of the causes of death, as well as of the births and marriages registered in Ireland during the year 1909. In the present instance the Lord Lieutenant has reverted to the custom, temporarily, and perhaps unavoidably, suspended on the occasion of the appointment of the late Dr. Grimshaw's successor—namely, that of selecting for the important office of Registrar-General a member of the medical profession, Sir William J. Thompson, who is a distinguished graduate of Trinity College and a physician-in-ordinary to the Lord Lieutenant of Ireland.

In noticing the appearance of the annual report for 1908 we congratulated Sir Robert Matheson on his promptitude in issuing that useful volume in time to be available for preventive purposes. We have now the pleasure of repeating to Sir William J. Thompson our congratulations; for his report, like that of his predecessor, has been published within little more than six months of the close of the period to which it relates. And we must reiterate the hope expressed in previous numbers of THE LANCET that equal promptitude may shortly be attained in the issue of similar information for other divisions of the kingdom. The assistance rendered by Dr. Ninian M. Falkiner in preparing the statistical portion of their reports has been gracefully acknowledged both by Sir William J. Thompson and by his predecessor. For several years past Dr. Falkiner has bestowed much labour on the analysis of Irish mortality and on the study of its causes, and he merits the praise accorded to him by each of his official superiors.

Vital Statistics.

According to the best available estimate, the population of the sister isle would seem to be decreasing. There is no official record concerning immigration, but the loss by emigration is put down at 28,676, whilst the natural increase of the population by excess of births over deaths did not exceed 27,786. There would therefore appear to have been a decrease of 890 in the population at the end of 1909. Compared with the decennial averages, the rates both of marriages and of births show a slight increase in the year referred to, but the rate of mortality has fallen by 0·6 per 1000 as compared with the same average. In the year 1909 the general death-rate in Ireland was equal to 17·2 per 1000 of the population, which was estimated at 4,371,570 at the middle of that year. As was also the case in England, the death-rates were highest in the more distinctly urban, and lowest in the rural, areas of Ireland. For example, whilst the rates did not exceed 13 1 per 1000 living in County Kerry and 13·5 in County Clare, they rose to 18·2 in Belfast, 18·9 in Armagh, and 23·4 in Dublin. Of the total deaths registered last year, 4·5 per cent. occurred in infirmaries or hospitals unconnected with the Poor-law, and 13·8 per cent. in workhouses or workhouse hospitals.

For several past years a prominent feature in Irish mortality has been the relative lowness of the rate among the younger portion of the community, the death-rate under the age of five years being only 33·16 in each 1000 living at that age. Corresponding data for 1909 in England and Wales are not yet available for comparison, but the average English rate at the same age in the ten years 1899–1908 was 48·9 per 1000.

In the present report the usual interesting table is repeated showing the occupation or social position of the persons whose deaths were reported in Dublin; it also shows the mortality at each of six periods of life, and the number of deaths from specified causes. From this table we gather that among the families of the professional and independent classes the annual death-rate from all causes was 16·5 per 1000 persons living in that class; among the middle-class (consisting of civil servants, clerks, commercial assistants, &c.) the rate was also 16·5; among the artisan class and petty shopkeepers the rate was 16·8; whilst among the general service class (including the army, police, domestic servants, coach and car drivers, and others above the rank of paupers) the rate was 23·0 per 1000 living.

Uncertified Deaths.—Ill-defined causes of Death.

Commenting on the subject of ill-defined and uncertified causes of death, the Registrar-General very properly appeals to the medical profession in Ireland for greater care in filling up their certificates of death. It is the desire, he urges, of all medical statisticians and advocates of sanitary improvement that the diseases and conditions causing death should be definitely and accurately recorded and legally certified for entry in the General Register Office. The high percentage of uncertified deaths is an undesirable feature of Irish vital statistics, and compares unfavourably with the figures for England and Scotland. In Ireland the proportion of uncertified to total deaths still stands at 25 per cent., whilst the percentages in England and Scotland are only 1·4 and 2·3 respectively.

To this report are appended the usual tables of causes of death according to the English model in vogue since 1901. Among general diseases, those which call for especial notice are pneumonia and tuberculosis. From the various forms of pneumonia the loss of life last year was higher than in any other year since 1899, nearly 6 per cent. of the total mortality having been due to that disease. In the year under notice the death-rate from pneumonia was equal to 99 per 100,000 living, having increased from 64 per 100,000 since the year 1888. Of the deaths from lobar pneumonia only 17 per cent., whilst of those from broncho-pneumonia more than 60 per cent., occurred in persons below the age of 20 years.

Decrease of Mortality from Tuberculous Disease.

From tuberculosis in all its forms a still further decrease in mortality is recorded in 1909—the number of deaths in that year having been 10,594, or fewer by 699 than in 1908, a reduction of more than 6 per cent. The Registrar-General attributes this result very largely to the educational work of the Countess of Aberdeen, as carried on under her patronage by the Women's National Health Association. In the year under notice the deaths from pulmonary tuberculosis numbered 8051; they were fewer by 460 than the number registered in the previous year, and were below the annual average in the decennium ending with 1908 by not less than 1288. It is important to note that according to Irish experience the loss

of life from pulmonary tuberculosis is nearly equal in both sexes, whereas English experience shows the mortality to be at the present time enormously greater among males, although this has not always been the case. In Ireland the greatest fatality from this disease occurs in the age-period 25–35 years, the death-rate among men being 3·78 per 1000 living, and among women 3·29 per 1000. In England pulmonary tuberculosis is most fatal to the male sex at the age-group 45–55 years, and to the female sex at the age-group 35–45 years. A highly interesting table is inserted in this report showing the mortality from tuberculous phthisis among the several social classes in the Dublin registration area. The figures refer to the year 1909. From this table we learn that the rate per 1000 living, represented by deaths from tuberculous phthisis among the families of the professional and independent class was 0·29, among the families of the middle class the rate was 1·76, among the families of the artisan class and petty shopkeepers it was 2·19, and among the families of the general service class it was 2·31.

Infantile Mortality.

In respect of infantile mortality—i.e., the rate of death under one year per 1000 births—Ireland compares favourably with the other divisions of the United Kingdom. The rate last year was 92 per 1000 in Ireland, whilst it was 109 in England and 121 in Scotland. Infantile mortality varies considerably in the urban as compared with the rural parts of Ireland, for whilst it amounted to 123 per 1000 in the "civic areas"—i.e., the unions containing towns with populations of not less than 10,000—it did not exceed 71 per 1000 in the remainder of Ireland. If the mortality in the principal urban districts of Ireland be contrasted with that in the country districts the differences in infantile mortality will be found to be still more pronounced. Thus in the Kilkenny urban district the rate amounted to as much as 155 per 1000 births (which is higher than the Liverpool rate for the same period), whilst in the sparsely-populated district of Tralee the rate was only 70 in each 1000 registered births.
